

# Inspecting the Structural Biases of Dependency Parsing Algorithms

Yoav Goldberg and **Michael Elhadad**

Ben Gurion University

ISCOL 2010, TAU

# Dependency Parsing

input: a sentence

"the input is a sentence"

output: dependency tree

We'll be using this notation

# Parsing Approaches

## Graph Based

- global inference
- expensive!  $O(n^3)++$
- edge factored features  
(add some more  
with high cost)

# Parsing Approaches

## Graph Based

- global inference
- expensive!  $O(n^3)++$
- edge factored features

## Transition Based

- Shift reduce variants
- Many local greedy actions
- Left to right
- Rich features
- Fast!  $O(n)$

# Parsing Approaches

## Graph Based

- global inference
- expensive!  $O(n^3)$ ++
- edge factored features

## Transition Based

- Shift reduce variants
- Many local greedy actions
- Left to Right
- Rich features
- fast!  $O(n)$

## Hybrids

- Voting
- Stacking
- blending

# Parsing Approaches

## Graph Based

- global inference
- expensive!  $O(n^3)$ ++
- edge factored features

Easy First

NEW!

Today.

## Hybrids

- Voting
- Stacking
- Blending

## Transition Based

- shift reduce variants
- Many local greedy features
- Left to Right
- Rich features
- fast!  $O(n)$

# Easy First Parsing

New!

greedy bottom up parser

~~left to right~~ → easy before hard

fast!  $O(n \log n)$

less error propagation

parser learns what's easy for it

## Motivation

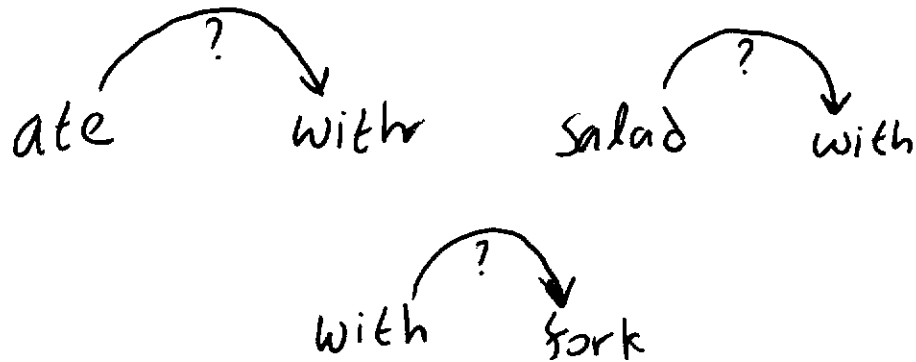

"the boy ate the salad with the shiny silver fork"

## Motivation

"the boy ate the salad with the shiny silver fork"

Graph Based → each edge scored separately

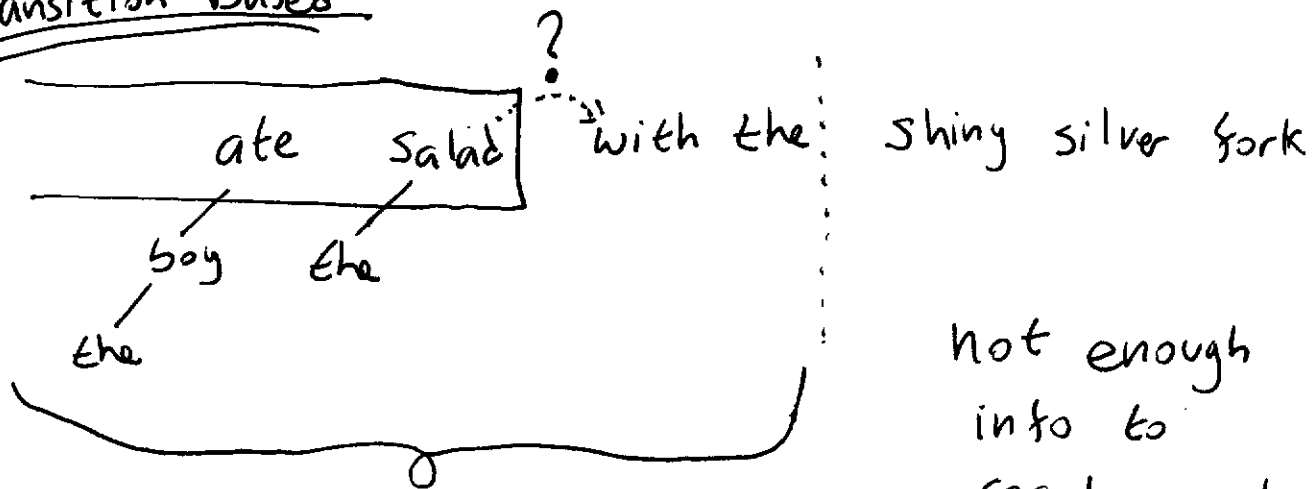

Not enough information to resolve ambiguity!

# Motivation

"the boy ate the salad with the shiny silver fork"

## Transition Based

parser sees up  
to here

not enough  
info to  
resolve ambiguity!

# Motivation

"the boy ate the salad with the shiny silver fork"

## Transition Based

ate salad

boy the  
the

?

with the shiny silver fork

but this is easy to parse

parser sees up  
to here

not enough  
info to  
resolve ambiguity!

# Motivation

"the boy ate the salad with the shiny silver fork"

## Easy First

# Motivation

"the boy ate the salad with the shiny silver fork"

Easy First

All needed information is available!

# Parsers

MST

Ryan McDonald

Graph Based  
(first order)

MALT

Joakim Nivre

Transition Based  
(arc-eager,  
poly. SVM  
classifier)

Easy First

This work

# Results

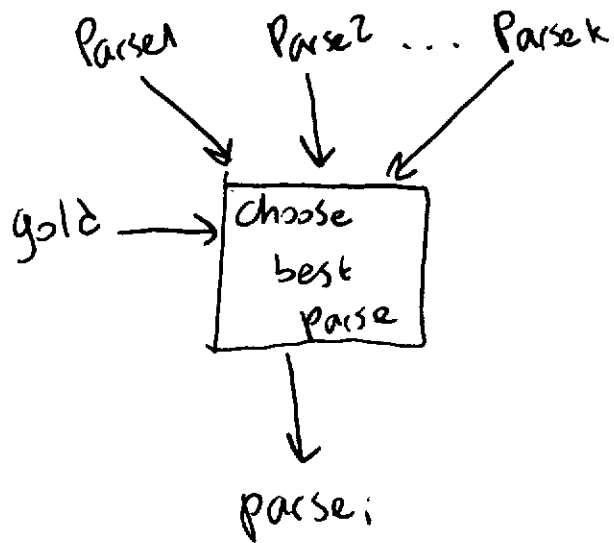

## WSJ

	unlabeled accuracy	root accuracy	Complete Sentence
Malt	88.36	87.04	34.16
MST	90.05	93.95	34.64
Easy First	89.70	91.50	37.5

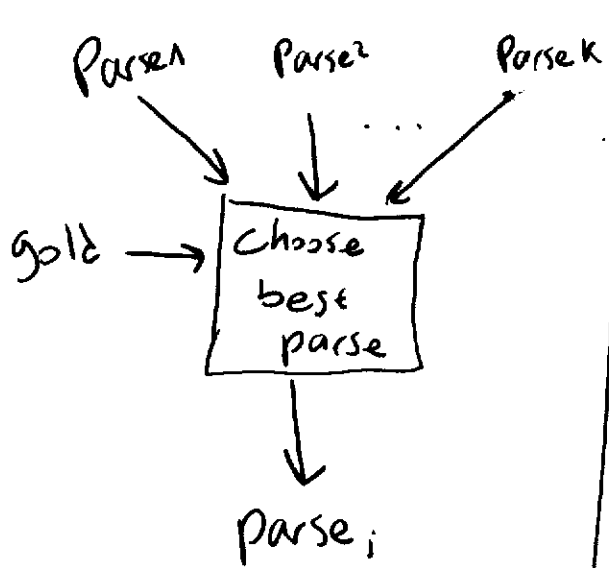

Our Parses are Different

# Parser Combination: Oracle

# Parser Combination: Oracle

	accuracy	complete
$M_{alt}+M_{ST}$	92.29	44.03
$Easy+M_{alt}$	92.19	45.48
$Easy+M_{st}$	92.53	44.41
$Easy+M_{alt}+M_{ST}$	93.54	49.79

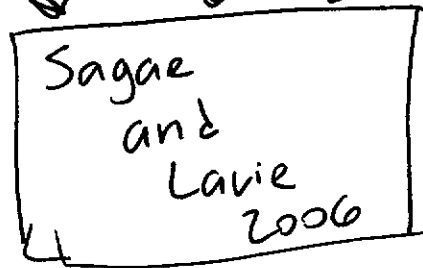

WSJ

Parser Combination: REAL

Malt                      MST                      EasyFirst

Sagae  
and  
Lavie  
2006

90.8

for CoNLL English

(Highest of all participants!)

... up until now

We can build many accurate parsers

- ▶ MALT, MST, CONLL 2007, EASYFIRST, Liang and Kenji's...

Parser combinations work

⇒ every parser has its strong points

Different parsers behave differently

# Previously

McDonald and Nivre 2007:

“Characterize the Errors of Data-Driven Dependency Parsing Models”

- ▶ Focus on **single-edge** errors
  - ▶ MST better for long edges, MALT better for short
  - ▶ MST better near root, MALT better away from root
  - ▶ MALT better at nouns and pronouns, MST better at others
- ▶ ...but all these differences are very small

we do something a bit different

# Assumptions

- ▶ Parsers fail in predictable ways
- ▶ those can be analyzed
- ▶ analysis should be done by inspecting **trends** rather than individual decisions

## Note: We do not do error analysis

- ▶ Error analysis is **complicated**
  - ▶ one error can yield another / hide another
- ▶ Error analysis is **local** to one tree
  - ▶ many factors may be involved in that single error

we are aiming at more global trends

# Structural preferences

# Structural preferences

## for a given language+syntactic theory

- ▶ Some structures are more common than others
  - ▶ (think Right Branching for English)
- ▶ Some structures are very rare
  - ▶ (think non-projectivity, OSV constituent order)

# Structural preferences

## **parsers also exhibit structural preferences**

- ▶ some are explicit / by design
  - ▶ e.g. projectivity
- ▶ some are implicit, stem from
  - ▶ features
  - ▶ modeling
  - ▶ data
  - ▶ interactions
  - ▶ and other stuff

**These trends are interesting!**

# Structural Bias

# Structural Bias

“The difference between the structural preferences of two languages”

For us:

*Which structures tend to occur more in language than in parser?*

# Bias vs. Error

related, but not the same

*Parser X makes many PP attachment errors*

- ▶ claim about error pattern

*Parser X tends to attach PPs low, while language Y tends to attach them high*

- ▶ claim about structural bias (and also about errors)

*Parser X can never produce structure Y*

- ▶ claim about structural bias

# Formulating Structural Bias

“given a tree, can we say where it came from?”

?

# Formulating Structural Bias

“given two trees of the same sentence, can we tell which parser produced each parse?”

?

# Formulating Structural Bias

“which parser produced which tree?”

any predictor that can help us answer this question is an indicator of structural bias

**uncovering structural bias = searching for good predictors**

# Method

- ▶ start with two sets of parses for same set of sentences
- ▶ look for predictors that allow us to distinguish between trees in each group

# Our Predictors

- ▶ all possible subtrees
- ▶ always encode:
  - ▶ part of speech
  - ▶ relations
  - ▶ direction
- ▶ can encode also:
  - ▶ lexical items
  - ▶ distance to parent

# Search Procedure

## boosting with subtree features

algorithm by Kudo and Matsumoto 2004.

### **very briefly:**

- ▶ **input: two sets of constituency trees**
- ▶ while not done:
  - ▶ choose a subtree that classifies most trees correctly
  - ▶ re-weight trees based on errors
- ▶ **output: weighted subtrees (= linear classifier)**

# Setup

Gold trees  
Parsed trees

train      validation

KJM  
2004

Weighted  
Subtrees  
= Classifier

ignore  
Weights

Subtrees

Rescore  
(Count based)

Bias Predictors

# conversion to constituency

mandatory information at node label  
optional information as leaves

# Experiments

## Analyzed Parsers

- ▶ Malt Eager
- ▶ Malt Standard
- ▶ Mst 1
- ▶ Mst 2

## Data

- ▶ WSJ (converted using Johansson and Nugues)
- ▶ splits: parse-train (15-18), boost-train (10-11), boost-val (4-7)
- ▶ gold pos-tags

# Quantitative Results

Q: Are the parsers biased with respect to English?

A: Yes

Parser	Train Accuracy	Val Accuracy
MST1	65.4	57.8
MST2	62.8	56.6
MALTE	69.2	65.3
MALTS	65.1	60.1

**Table:** Distinguishing parser output from gold-trees based on structural information

# Qualitative Results (teasers)

Over-produced by ArcEager:

ROOT→“    ROOT→DT    ROOT→WP

(we knew it's bad at root, now we know how!)

# Qualitative Results (teasers)

Over-produced by ArcEager and ArcStandard

$\rightarrow \text{VBD} \xrightarrow{9+} \text{VBD}$

$\rightarrow \text{VBD} \xrightarrow{5-7} \text{VBD}$

ROOT  $\rightarrow$  VBZ  $\rightarrow$  VBZ

(prefer first verb above second one: because of left-to-right processing? )

# Qualitative Results (teasers)

Over-produced by MST1

(independence assumption failing)

# Qualitative Results (teasers)

Under-produced by MST1 and MST2

(hard time in coordinating “heavy” NPs: due to *pos-in-between* feature?)

# Qualitative Results (teasers)

## Software available

Try with your language / parser

# To Conclude

- ▶ understanding HOW parsers behave and WHY is important
  - ▶ we should do more of that
- ▶ we defined structural bias as way of characterizing behaviour
- ▶ we presented an algorithm for uncovering structural bias
- ▶ applied to English with interesting results
