Natural Language Processing

Feature-rich models

Based on slides from Michael Collins and Yoav Artzi
Motivation
Back to language modeling

- Goal: estimate a distribution \( p(w_i | w_1, w_2, \ldots, w_{i-1}) \)
- Example (Chomsky, 1950):

Third, the notion “grammatical in English” cannot be identified in any way with the notion “high order statistical approximation to English”. It is fair to assume that neither sentence (1) nor (2) (nor indeed any part of these sentences) has ever occurred in an English discourse. Hence in any statistical ______
Trigram models

Third, the notion “grammatical in English” cannot be identified in any way with the notion “high order statistical approximation to English”. It is fair to assume that neither sentence (1) nor (2) (nor indeed any part of these sentences) has ever occurred in an English discourse. Hence in any statistical _______

\[ q_{LI}(\text{model} \mid w_{i-2}, w_{i-1}) = \lambda_1 \times q(\text{model} \mid w_{i-2} = \text{any}, w_{i-1} = \text{statistical}) + \lambda_2 \times q(\text{model} \mid w_{i-1} = \text{statistical}) + \lambda_3 \times q(\text{model}) \]

\[ \lambda_i \geq 0, \quad \lambda_1 + \lambda_2 + \lambda_3 = 1 \]

\[ q(y \mid x) = \frac{c(x, y)}{c(x)} \]
Problems

• We use unigrams, bigrams and trigrams information

• But there is a lot of other information (“features”):

\[
\begin{align*}
q(\text{model} \mid w_{i-2} = \text{any}) \\
q(\text{model} \mid w_{i-1} \text{ is an adjective}) \\
q(\text{model} \mid w_{i-1} \text{ ends in “ical”}) \\
q(\text{model} \mid \text{author is Chomsky}) \\
q(\text{model} \mid \text{“model” does not occur in } w_1, \ldots, w_{i-1}) \\
\end{align*}
\]
Naive approach

\[ \lambda_1 q(\ldots) + \lambda_2 q(\ldots) \cdots + \lambda_F q(\ldots) \]

- Estimate a ML model for each information piece
- Interpolate and learn the coefficient
  - Is this scalable?
Profits soared at Boeing Co., easily topping forecasts on Wall Street, as their CEO Alan Mulally announced first quarter results.

Profits/N soared/V at/P Boeing/N Co./N ,/ , easily/Adv topping/V forecasts/N on/P Wall/N Street/N ,/ , as/P their/Poss CEO/N Alan/N Mulally/N announced/V first/Adj quarter/N results/N ./.

N: noun
V: verb
P: preposition
Adv: adverb
Adj: adjective
...
Tagging

• We learned to estimate \( p(x, y) \)

• We want to define a model that directly estimates \( p(y \mid x) \)

  • Why?

\[
p(y_1, \ldots, y_n \mid x_1, \ldots, x_n, y_{-1}, y_0) = p(y_1 \mid y_{-1}, y_0, x_1, \ldots, x_n) \\
  \times p(y_2 \mid y_{-1}, y_0, y_1, x_1, \ldots, x_n) \\
  \vdots \\
  \times \ldots p(y_n \mid y_{-1}, \ldots, y_{n-1}, x_1, \ldots, x_n) \\
= \prod_{i=1}^{n} p(y_i \mid y_{-1}, \ldots, y_{i-1}, x_1, \ldots, x_n)
\]
Tagging

• We want a model

\[ p(y_i \mid y_1 \cdots y_{i-1}, x_1, \cdots, x_n) \]

Hispaniola/NNP quickly/RB became/VB an/DT important/JJ base/?? from which Spain expanded its empire into the rest of the Western Hemisphere.

• This is a multi-class problem with classes NN, NNS, Vt, Vi, IN, DT, …
Information pieces

- $q(\text{NN} \mid x_i=\text{base})$ : local feature
- $q(\text{NN} \mid y_{i-1} \text{ is JJ})$: context feature
- $q(\text{NN} \mid x_i \text{ ends in “e”})$
- $q(\text{NN} \mid x_i \text{ ends in “se”})$
- $q(\text{NN} \mid w_{i-1} \text{ is “important”})$
- $q(\text{NN} \mid w_{i+1} \text{ is “from”})$
Features in log-linear models
Definition

- Input: domain $X$
  - All document prefixes (LM)
  - What is it in tagging?
- Input: finite label set
  - words in vocabulary (LM)
  - tag set in tagging
- Output a model $p(y \mid x)$
Features

• A feature is a function from \((x, y)\) to a real value:

\[
f_k(x, y) \in \mathbb{R}
\]

\[
f_k(x, y) \in \{0, 1\}
\]

• A feature vector holds \(m\) features

\[
f(x, y) = \langle f_1(x, y), f_2(x, y), \ldots, f_m(x, y) \rangle
\]
Third, the notion “grammatical in English” cannot be identified in any way with the notion “high order statistical approximation to English”. It is fair to assume that neither sentence (1) nor (2) (nor indeed any part of these sentences) has ever occurred in an English discourse. Hence in any statistical _______

\[ f_1(x, y) = \begin{cases} 
1 & \text{if } y = \text{model} \\
0 & \text{otherwise}
\end{cases} \]

\[ f_2(x, y) = \begin{cases} 
1 & \text{if } y = \text{model}, \ x_{i-1} = \text{statistical} \\
0 & \text{otherwise}
\end{cases} \]

\[ f_3(x, y) = \begin{cases} 
1 & \text{if } y = \text{model}, \ x_{i-1} = \text{statistical}, \ x_{i-2} = \text{any} \\
0 & \text{otherwise}
\end{cases} \]
More features

\[ f_4(x, y) = \begin{cases} 
1 & \text{if } y = \text{model, } x_{i-2} = \text{any} \\
0 & \text{otherwise}
\end{cases} \]

\[ f_5(x, y) = \begin{cases} 
1 & \text{if } y = \text{model, } x_{i-1} \text{ is an adjective} \\
0 & \text{otherwise}
\end{cases} \]

\[ f_6(x, y) = \begin{cases} 
1 & \text{if } y = \text{model, } x_{i-1} \text{ ends with "ical"} \\
0 & \text{otherwise}
\end{cases} \]

\[ f_7(x, y) = \begin{cases} 
1 & \text{if } y = \text{model, author is Chomsky} \\
0 & \text{otherwise}
\end{cases} \]
Feature templates

• If we have a feature over pairs or triples of objects then we would have a feature for every possible combination.

• For example, for every triple of words $u, v, w$ that appears in the training data we have a feature:

$$f_{N(u,v,w)}(x, y) = \begin{cases} 
1 & \text{if } y = w, x_{i-1} = v, x_{i-2} = u \\
0 & \text{otherwise}
\end{cases}$$

• $N(u,v,w)$ is a hashing function from the word triple to an non-negative integer.
Tagging features

\[ x = \langle y_1, \ldots, y_{i-1}, x_1, \ldots, x_n, i \rangle \]
\[ y \in S \ (\text{NN, NNS, ...}) \]
\[ f(x, y) \in \mathbb{R}^m \]

\[
f_1(x, y) = \begin{cases} 
1 & \text{if } x_i = \text{base and } y = \text{Vt} \\
0 & \text{otherwise}
\end{cases}
\]

\[
f_2(x, y) = \begin{cases} 
1 & \text{if } x_i \text{ ends in "ing" and } y = \text{VBG} \\
0 & \text{otherwise}
\end{cases}
\]

• Use feature templates for pairing all word/tag pairs or all suffix/tag pairs
Feature representation

- Feature vectors are sparse - mostly zeros

- How many features are on in a LM with trigram, bigram and unigram feature templates?

- Represent with hash maps (or hash sets if all features are binary):

\[ f(\langle JJ, DT, \langle Hispaniola, \ldots \rangle, 6, Vt \rangle) = \{121, 1003, 21554\} \]
\[ f(\langle JJ, DT, \langle Hispaniola, \ldots \rangle, 6, JJ \rangle) = \{3, 115, 2051\} \]

- Efficient in memory and dot-product computation (\( f' \) is a dense representation and \( f'' \) is a sparse one)

\[
f(x, y) \top \theta = \sum_k f'_k(x, y) \cdot \theta_k = \sum_{k \in f''_k(x, y)} \theta_k
\]
Conditional model

- We use the features to define a score for every possible label

\[ s(x, y) = f(x, y)^\top \theta = \sum_k f_k(x, y) \cdot \theta_k, \quad \theta \in \mathbb{R}^m, f(x, y) \in \mathbb{R}^m \]

- We can now define a conditional probability \( p(y \mid x) \)

\[
p_\theta(Y = y \mid x) = \frac{e^{s(x, y)}}{\sum_{y' \in Y} e^{s(x, y')}} = \text{softmax}(s(x, y_1), s(x, y_2), \ldots s(x, y_{|Y|}))
\]

\[
(1, 2, 3, 4) \rightarrow \left( \frac{e^1}{e^1 + e^2 + e^3 + e^4}, \frac{e^2}{e^1 + e^2 + e^3 + e^4}, \frac{e^3}{e^1 + e^2 + e^3 + e^4}, \frac{e^4}{e^1 + e^2 + e^3 + e^4} \right) \\
= (0.032, 0.087, 0.237, 0.644)
\]
Relation to deep learning

• Neural networks for multi-class classification often have a softmax layer at the top

• Log-linear models:
  • Use human knowledge to write down features that will allow a linear decision boundary

• Deep learning models:
  • Learn features with the neural net that will allow a linear decision boundary
Log-linear models

• **Input**: domain \( X \), Input label set \( Y \)

• **Feature function**:

\[
f : \mathcal{X} \times \mathcal{Y} \rightarrow \mathbb{R}^m
\]

• **Parameters**:

\[
\theta \in \mathbb{R}^m
\]

• **Output**: \( p(y \mid x) \)

\[
p_\theta(y \mid x) = \frac{e^{f(x,y)^\top \theta}}{\sum_{y' \in \mathcal{Y}} e^{f(x,y')^\top \theta}}
\]
Why log-linear? well…

\[
\log p_\theta(y \mid x) = \\
\log e^{f(x,y)^\top \theta} - \log \sum_{y' \in \mathcal{Y}} e^{f(x,y')^\top \theta} = \\
f(x, y)^\top \theta - \log \sum_{y' \in \mathcal{Y}} e^{f(x,y')^\top \theta}
\]

- First term is linear in parameters
- Second term does not depend on $y$
Parameter estimation
Maximum likelihood

- **Input:** training examples

\[ \{(x^{(i)}, y^{(i)})\}_{i=1}^{n}, \quad (x^{(i)}, y^{(i)}) \in \mathcal{X} \times \mathcal{Y} \]

- **Objective function:**

\[
L(\theta) = \sum_{i=1}^{n} \log p_{\theta}(y^{(i)} | x^{(i)}) = \sum_{i=1}^{n} f(x^{(i)}, y^{(i)})^\top \theta - \sum_{i=1}^{n} \log \sum_{y' \in \mathcal{Y}} e^{f(x^{(i)}, y')^\top \theta}
\]

\[\theta_{\text{ML}} = \arg \max_{\theta} L(\theta)\]
Optimization

• L is a concave function (sum of concave functions)

• Can find optimal point with gradient-based methods
Computing the gradient

• Let’s look at one example

\[
\frac{\partial L^{(i)}(\theta)}{\theta_k} = f_k(x^{(i)}, y^{(i)}) - \frac{1}{\sum_{z' \in \mathcal{Y}} e f(x^{(i)}, z')^{\top} \theta} \cdot \frac{\partial \left( \sum_{y' \in \mathcal{Y}} e f(x^{(i)}, y')^{\top} \theta \right)}{\partial \theta_k} \\
= f_k(x^{(i)}, y^{(i)}) - \frac{\sum_{y' \in \mathcal{Y}} e f(x^{(i)}, y')^{\top} \theta \cdot f_k(x^{(i)}, y')}{\sum_{z' \in \mathcal{Y}} e f(x^{(i)}, z')^{\top} \theta} \\
= f_k(x^{(i)}, y^{(i)}) - \sum_{y' \in \mathcal{Y}} f_k(x^{(i)}, y') \cdot \frac{e f(x^{(i)}, y')^{\top} \theta}{\sum_{z' \in \mathcal{Y}} e f(x^{(i)}, z')^{\top} \theta} \\
= f_k(x^{(i)}, y^{(i)}) - \sum_{y' \in \mathcal{Y}} f_k(x^{(i)}, y') \cdot p_\theta(y' \mid x) \\
= f_k(x^{(i)}, y^{(i)}) - \mathbb{E}_{y' \sim p_\theta} [f_k(x, y')] \\
\]

• Add empirical count and subtract expected counts under the model
SGD vs. perceptron

• Input: \((x, y)\)

• SGD

\[
\theta_{\text{new}} = \theta_{\text{old}} + \eta \cdot (f(x, y) - \mathbb{E}_{y' \sim p_{\theta_{\text{old}}}}[f(x, y')])
\]

• Perceptron

\[
\theta_{\text{new}} = \theta_{\text{old}} + f(x, y) - f(x, \arg \max_{y'} f(x, y')^\top \theta_{\text{old}})
\]

• What are the differences? In practice Averaged perceptron is usually used.
Side note

- Many other optimization techniques exist
  - Line search
  - Coordinate ascent
  - Conjugate methods
  - Second-order and quasi-second order methods
  - …
Regularization

• Say the word “base” appears exactly twice in the training data and it is tagged as Vt in both times

\[ f_{100}(x, y) = \begin{cases} 
0 & \text{if } y = Vt \text{ and } x_i = \text{base} \\
1 & \text{otherwise} 
\end{cases} \]

• The gradient with respect to \( \theta_{100} \) are zero when:

\[
\sum_{i=1}^{n} f_{100}(x^{(i)}, y^{(i)}) = \sum_{i=1}^{n} \sum_{y' \in \mathcal{Y}} p_{\theta}(y' \mid x) \cdot f_{100}(x^{(i)}, y')
\]

• This happens when \( \theta_{100} \rightarrow \infty \): will not affect any other training example ==> bad generalization
L2 regularization

\[ L(\theta) = \sum_{i=1}^{n} \log p_{\theta}(y^{(i)} | x^{(i)}) + \lambda \cdot ||\theta||^2 \]

- Penalize large parameter values
- Empirically this allows using millions of features
Example for language modeling

• With n-gram features with no regularization:
  • The solution is exactly the ML estimate we saw in generative models

• With regularization
  • Empirical performance is slightly better than discounting methods

Learn a function from sentences to tag sequences
Option 1: HMMs

\[ p(x_1, \ldots, x_n, y_1 \ldots, y_n, \text{STOP}) = \]

\[ q(\text{STOP} \mid y_{n-1}, y_n) \times \prod_{i=1}^{n} q(y_i \mid y_{i-2}, y_{i-1}) \cdot e(x_i \mid y_i) \]

\[ y_0 = y_{-1} = * \]
HMMs

• **Properties:**
  
  • Generative model
  
  • Uses transition and emission probabilities
  
  • **Training:** count co-occurrences
  
  • **Decoding:** Viterbi algorithm
  
  • Score: 96.5 acc. on POS-tagging

• **Disadvantages:**

  • Hard to incorporate rich features
  
  • Need to model the data distribution \( p(x,y) \) instead of \( p(y \mid x) \)
Option 2: Log-linear model

- **Input**: domain $X$, label set $Y$

- **Feature function and parameters**: 
  \[ f : X \times Y \rightarrow \mathbb{R}^m \quad \theta \in \mathbb{R}^m \]

- **Model**: 
  \[
  p_\theta(y \mid x) = \frac{e^{f(x,y)\top\theta}}{\sum_{y' \in Y} e^{f(x,y')\top\theta}}
  \]

- Allow arbitrary features
- No need to model data distribution

Extremely common in many NLP tasks!
Log-linear model for tagging

- Input is a sentence \( w \) and label is a tag sequence \( t \)

- We define a log-linear model \( p(t_i \mid w, t_{-1} \ldots t_{i-1}) \)

\[
p(t_1, \ldots, t_n \mid w_1, \ldots, w_n, t_{-1}, t_0) = p(t_1 \mid t_{-1}, t_0, w_1, \ldots, w_n) \\
\times p(t_2 \mid t_{-1}, t_0, t_1, w_1, \ldots, w_n) \\
\vdots \\
\times \ldots p(t_n \mid t_{-1}, \ldots, t_{n-1}, w_1, \ldots, w_n) \\
= \prod_{i=1}^{n} p(t_i \mid t_{-1}, \ldots, t_{i-1}, w_1, \ldots, w_n)
\]
Independence assumption

- Markov assumption again:

\[
p(t_1, \ldots, t_n \mid w_1, \ldots, w_n, t_{-1}, t_0) = \prod_{i=1}^{n} p(t_i \mid t_{-1}, \ldots, t_{i-1}, w_1, \ldots, w_n)
\]

\[
= \prod_{i=1}^{n} p(t_i \mid t_{i-2}, t_{i-1}, w_1, \ldots, w_n)
\]

- Question: what will we lose if we don’t make this assumption?

- This is called a **locally normalized** log-linear model

  - Why?
Example

Hispaniola/NNP quickly/RB became/VB an/DT important/JJ base/?? from which Spain expanded its empire into the rest of the Western Hemisphere.

• A **history** \( x \) is a 4-tuple \(<t_{i-2}, t_{i-1}, w, i>\)

• A **label** \( y \) is \( t_i \).

\[
\begin{align*}
  t_{i-2} : & \text{DT} \\
  t_{i-1} : & \text{JJ} \\
  w : & \text{Hispaniola ... Hemisphere} \\
  i : & 6 \\
  t_i : & \text{NN}
\end{align*}
\]
Training

• Given training set of sentences and tag sequences \( w^{(j)}, t^{(j)} \), \( j = 1 \ldots n \)

• Build a training set of the form \( x^{(i)}, y^{(i)} \) by constructing all history/label pairs.

• Maximize the L2-regularized maximum-likelihood estimate

• Gradient is the difference between the empirical expected feature vector and model expected feature vector

\[
L(\theta) = \sum_{i=1}^{n} \log p_\theta(y^{(i)} \mid x^{(i)}) + \lambda \cdot \|\theta\|^2
\]
Decoding
Greedy

- Greedy decoding

- For $i = 1 \ldots n$
  - Choose $t_i$ with maximal probability

- This failed in generative models, but works pretty well here. Why?

- Complexity?

- Can we drop some independence assumptions?
Beam search

- Beam search
  - Keep a set of $K$ current hypotheses
  - For $i = 1 \ldots n$
    - Consider all continuations $t_i$ of current set of hypotheses $t_1 \ldots t_{i-1}$ and score them
  - Keep the top $K$

Fed raises interest rates 0.5 percent
Viterbi

• After training the log-linear model we obtain:

\[ p_\theta(y \mid x) = p_\theta(t_i \mid t_{i-2}, t_{i-1}, w, i) \]

• Our goal in decoding is to solve:

\[
\arg\max_{t_1, \ldots, t_n} \prod_{i=1}^{n} p(t_i \mid t_{i-2}, t_{i-1}, w, i)
\]

• Solution: Features depend on local hidden variables and so we can use Viterbi
Viterbi

• Define the probability of a tag prefix

\[ r(t_1, \ldots, t_k) = \prod_{i=1}^{k} p_{\theta}(t_i \mid t_{i-2}, t_{i-1}, w, i) \]

• Define the dynamic programming chart/table:

  • Maximum probability for a tag sequence of length \( k \) ending in \( u, v \)

\[ \pi(k, u, v) = \max_{t_1, \ldots, t_{k-2}} r(t_1, \ldots, t_k) \]
Viterbi

Definition: $S_k$ is the set of possible tags in position $k$

Base: $\pi(0, *, *) = 1$

for all $k \in \{1 \ldots n\}$, for all $u \in S_{k-1}, v \in S_k$:

$$\pi(k, u, v) = \max_{t \in S_{k-2}} \pi(k - 1, t, u) \times q(v | t, u, w, k)$$

- **Correctness**: again any sequence ending in triples $t,u,w$ in position $k$, must go through the highest probability sequence ending in $t,u$ in position $k-1$

- **Space and time complexity**: just like HMMs
  - Time $O(n|S|^3)$, Space $O(n|S|^2)$
Add backpointers

**Definition:** $S_k$ is the set of possible tags in position $k$.

**Base:** $\pi(0, *, *) = 1$

for all $k \in \{1 \ldots n\}$, for all $u \in S_{k-1}, v \in S_k$:

$$\pi(k, u, v) = \max_{t \in S_{k-2}} \pi(k - 1, t, u) \times q(v \mid t, u, w, k)$$

$$bp(k, u, v) = \arg \max_{t \in S_{k-2}} \pi(k - 1, t, u) \times q(v \mid t, u, w, k)$$

$$(y_{n-1}, y_n) = \arg \max_{u, v} \pi(n, u, v)$$

for $k = (n - 2) \ldots 1$, $y_k = bp(k + 2, y_{k+1}, y_{k+2})$
Ratnaparkhi, 1996

• Feature templates for
  • word/tag pairs
  • prefixes <5/tag pairs
  • suffixes <5/tag pairs
  • tag trigrams
  • tag bigrams
  • tag unigrams
  • word/tag pairs for previous word
  • word/tag pairs for subsequent word
Greedy vs. Viterbi

• What are the advantages of using greedy?
  • Faster
  • Feature function not constrained to the previous two tags

• What are the advantages of Viterbi
  • Global inference
  • Does not suffer from error propagation at test time
Greedy vs. Viterbi

MEMM vs. HMM

• McCallum et al. (2000) compared the two in a task of FAQ segmentation
  • Modeling word generation is hard
  • Tags: head, question, answer

  <answer>agreed upon by commercial comms software developers fo
  <answer>
  <answer> Pins 1, 4, and 8 must be connected together inside
  <answer>is to avoid the well known serial port chip bugs. The
MEMM

• Current tag is $t$, previous tag is $t'$ and
  • Line begins with number/punctuation/wh-word…
  • Line contains …
  • Line ends with …
  • Line indentation is
Token HMM

- Generate each word in the sentence independently from other words given the tag seems bad

<question>2.6) What configuration of serial cable should I use

\[ p(\text{“2.6) What configuration…”}| \text{question}) = p(\text{“2.6”}| \text{question}) \times p(\text{“What”}| \text{question}) \times p(\text{“configuration”}| \text{question}) \times \ldots \]
Feature HMM

• Replace words with features and then generate:

\[
p(\text{“2.6) What configuration...”}| \text{question}) = \\
p(\text{begins-with-number}| \text{question}) \times \\
p(\text{wh-word}| \text{question}) \times \\
p(\text{contains-alphanum}| \text{question}) \times \\
\ldots
\]

</tbody>
</table>

- **Precision**: number of correct segments predicted divided by total number of segments predicted
- **Recall**: Number of correct segments predicted divided by total number of true segments

Rich overlapping features help a lot!

And then also deep learning variants!
Summary

• Decompose a tag sequence to a sequence of “decisions”

• Train a log-linear model for making local decisions

• Decode with Viterbi
  • Or greedy
  • Or beam search
