Lecture 11

Assemblers, linkers, loaders

Noam Rinetzky

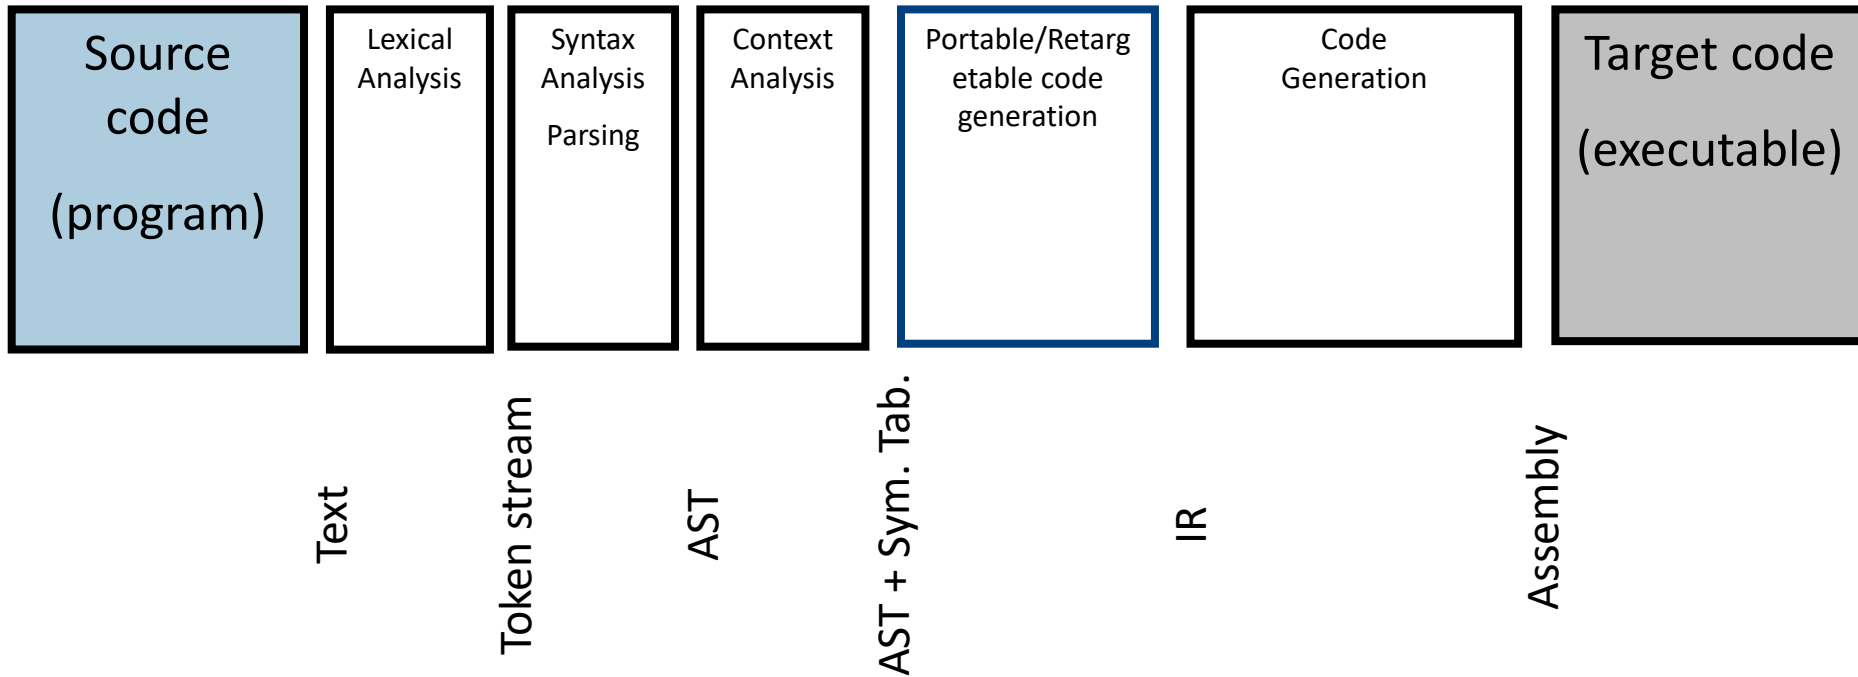

What is a compiler?

“A compiler is a computer program that transforms source code written in a programming language (source language) into another language (target language).

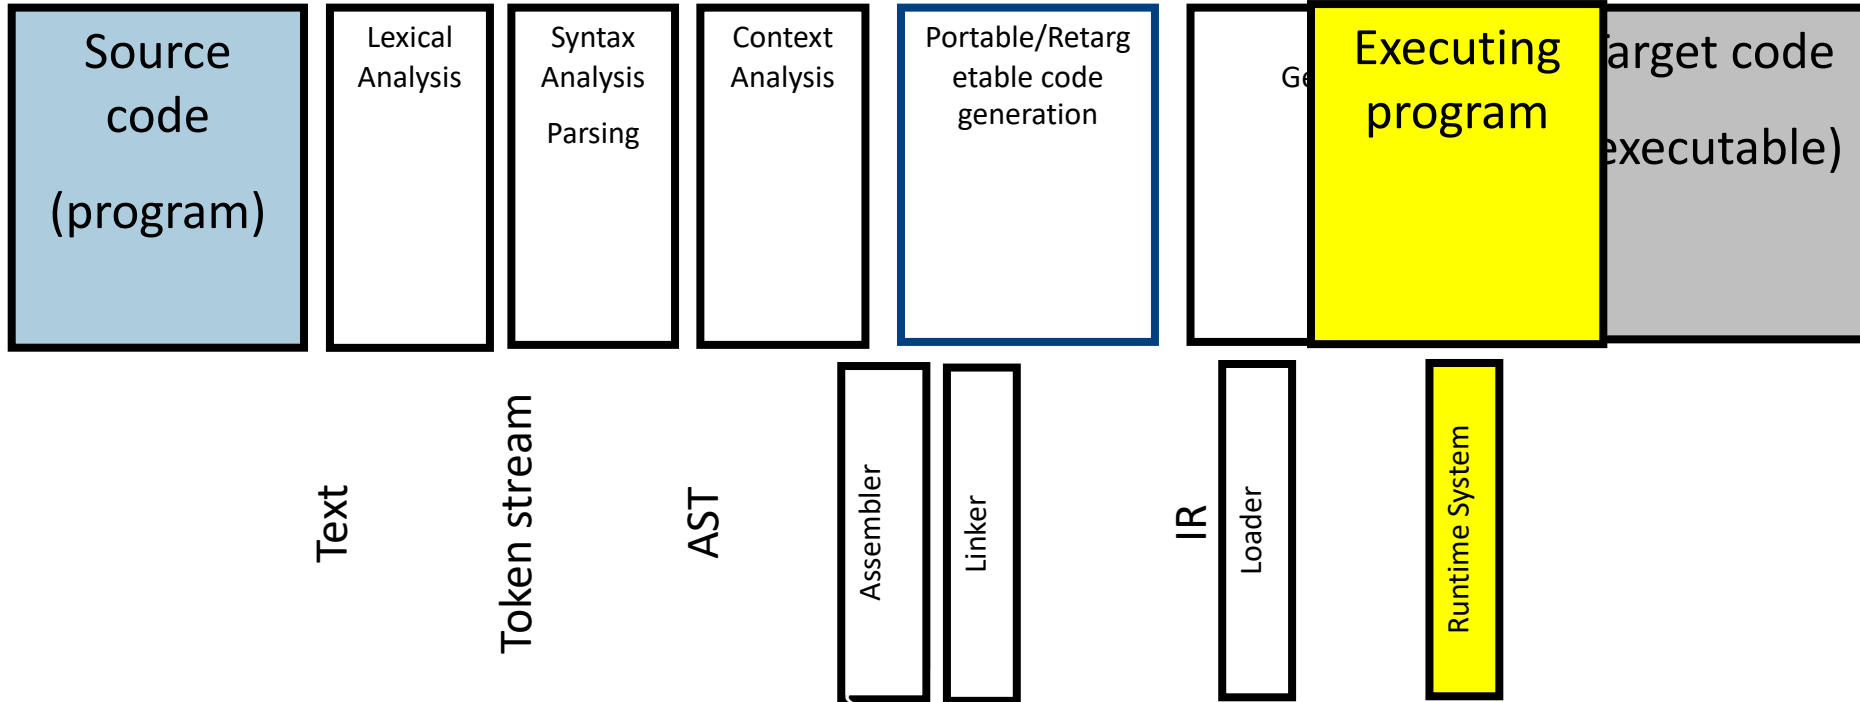

The most common reason for wanting to transform source code is to create an executable program.”

--Wikipedia

Stages of compilation

Compilation → Execution

Program Runtime State

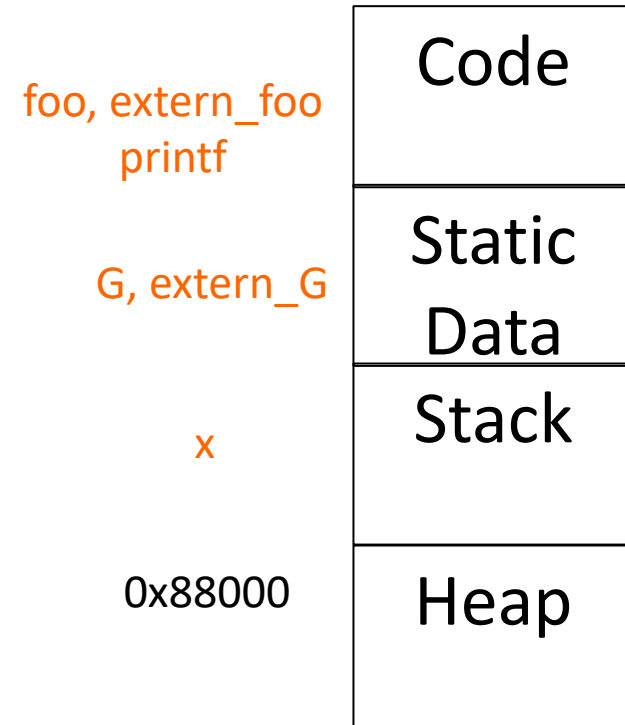

Registers

0x11000 foo, extern_foo printf	Code
0x22000 G, extern_G	Static Data
0x33000 x	Stack
0x88000 0x99000	Heap

Challenges

- goto L2 → JMP 0x110FF
- G:=3 → MOV 0x2200F, 0..011
- foo() → CALL 0x130FF
- extern_G := 1 → MOV 0x2400F, 0..01
- extern_foo() → CALL 0x140FF
- printf() → CALL 0x150FF

- x:=2 → MOV FP+32, 0...010
- goto L2 → JMP [PC +] 0x000FF

Assembly → Image

Source program

Compiler

Assembly lang. program (.s)

Assembler

Machine lang. Module (.o): program (+library) modules

Linker

“compilation” time

Executable (“.exe”):

“execution” time

Loader

Image (in memory):

Libraries (.o)
(dynamic loading)

Assembly → Image

Source file (*e.g., utils*)

Compiler

Assembly (.s)

Assembler

Object (.o)

Source file (*e.g., main*)

Compiler

Assembly (.s)

Assembler

Object (.o)

library

Compiler

Assembly (.s)

Assembler

Object (.o)

Linker

Executable (“elf”)

Loader

Image (in memory):

Outline

- Assembly
- Linker / Link editor
- Loader

- Static linking
- Dynamic linking

Assembler

- Converts (symbolic) assembler to binary (object) code
 - Object files contain a combination of machine instructions, data, and information needed to place instructions properly in memory
 - Yet another (simple) compiler
 - One-to one translation
- Converts constants to machine repr. (3 → 0...011)
- Resolve internal references
- Records info for code & data relocation

Object File Format

Header	Text Segment	Data Segment	Relocation Information	Symbol Table	Debugging Information
--------	--------------	--------------	------------------------	--------------	-----------------------

- Header: Admin info + “file map”
- Text seg.: machine instruction
- Data seg.: (Initialized) data in machine format
- Relocation info: instructions and data that depend on absolute addresses
- Symbol table: “exported” references + unresolved references

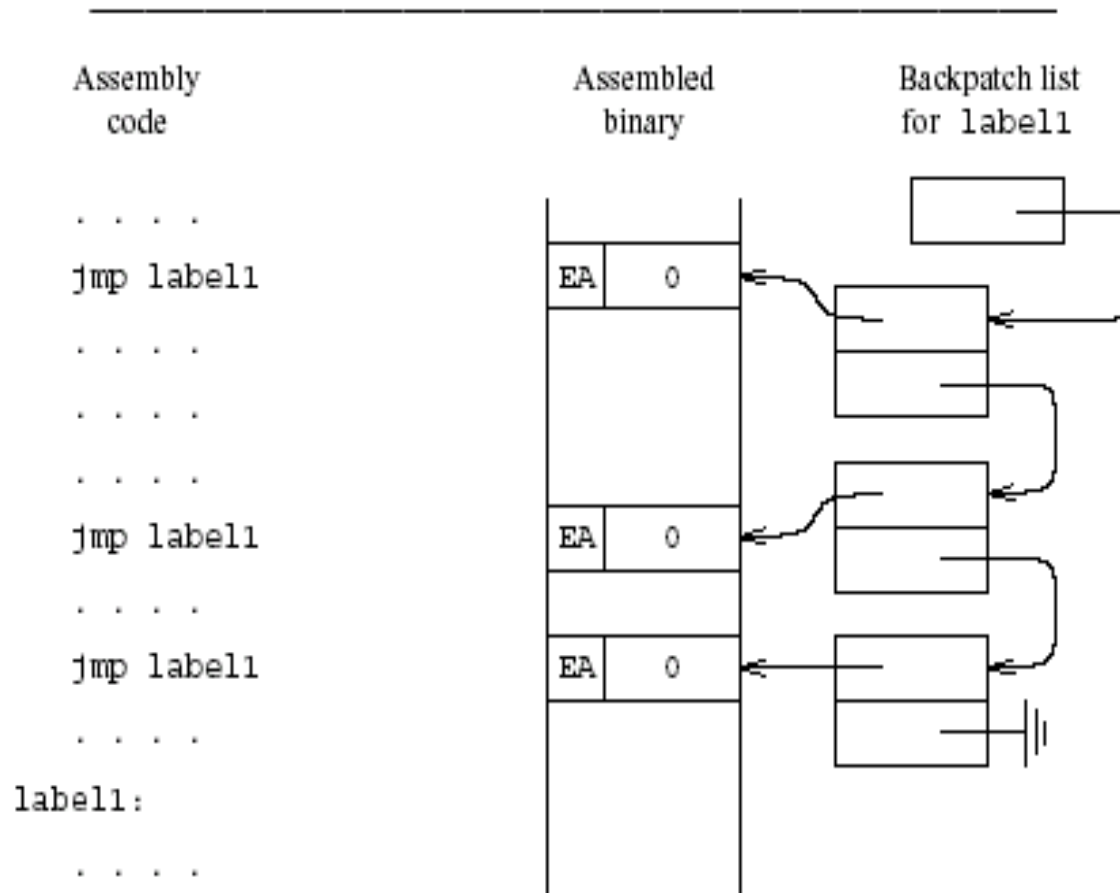

Handling Internal Addresses

```
.data
    ...
    .align 8
var1:
    .long 666
    ...
.code
    ...
    addl var1,%eax
    ...
    jmp label1
    ...
label1:
    ...
    ...
```

Resolving Internal Addresses

- Two scans of the code
 - Construct a table label → address
 - Replace labels with values
- One scan of the code (Backpatching)
 - Simultaneously construct the table and resolve symbolic addresses
 - Maintains list of unresolved labels
 - Useful beyond assemblers

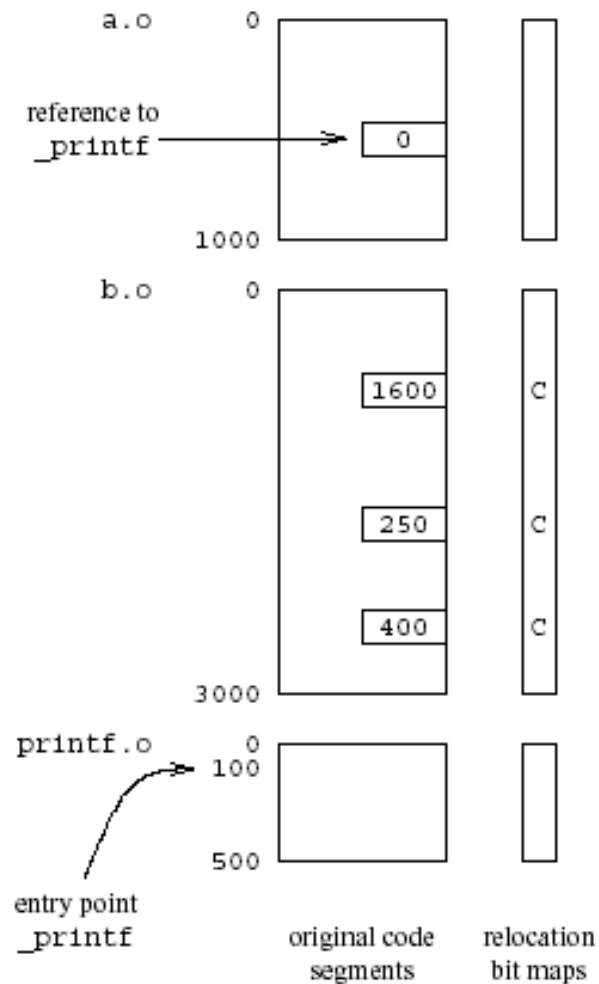

Backpatching

Handling External Addresses

- Record symbol table in “external” table
 - Exported (defined) symbols
 - G, foo()
 - Imported (required) symbols
 - Extern_G, extern_bar(), printf()
- Relocation bits
 - Mark instructions that depend on absolute (fixed) addresses
 - Instructions using globals

Example

External references resolved by the Linker using the relocation info.

Example of External Symbol Table

External symbol	Type	Address
_options	entry point	50 data
__main	entry point	100 code
_printf	reference	500 code
_atoi	reference	600 code
_printf	reference	650 code
_exit	reference	700 code
_msg_list	entry point	300 data
_Out_Of_Memory	entry point	800 code
_fprintf	reference	900 code
_exit	reference	950 code
_file_list	reference	4 data

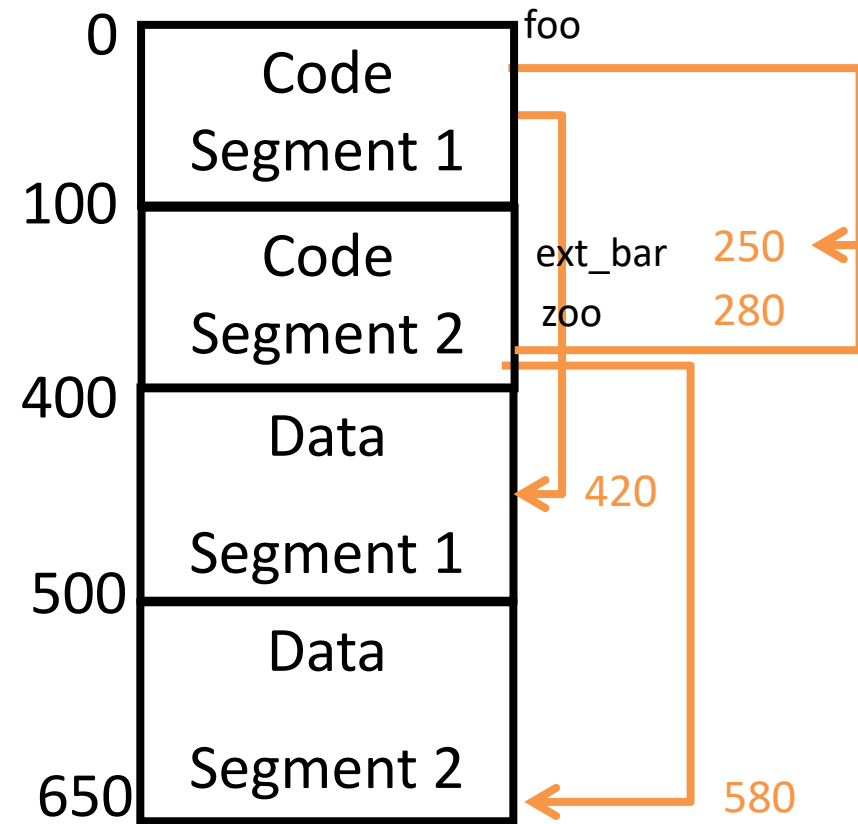

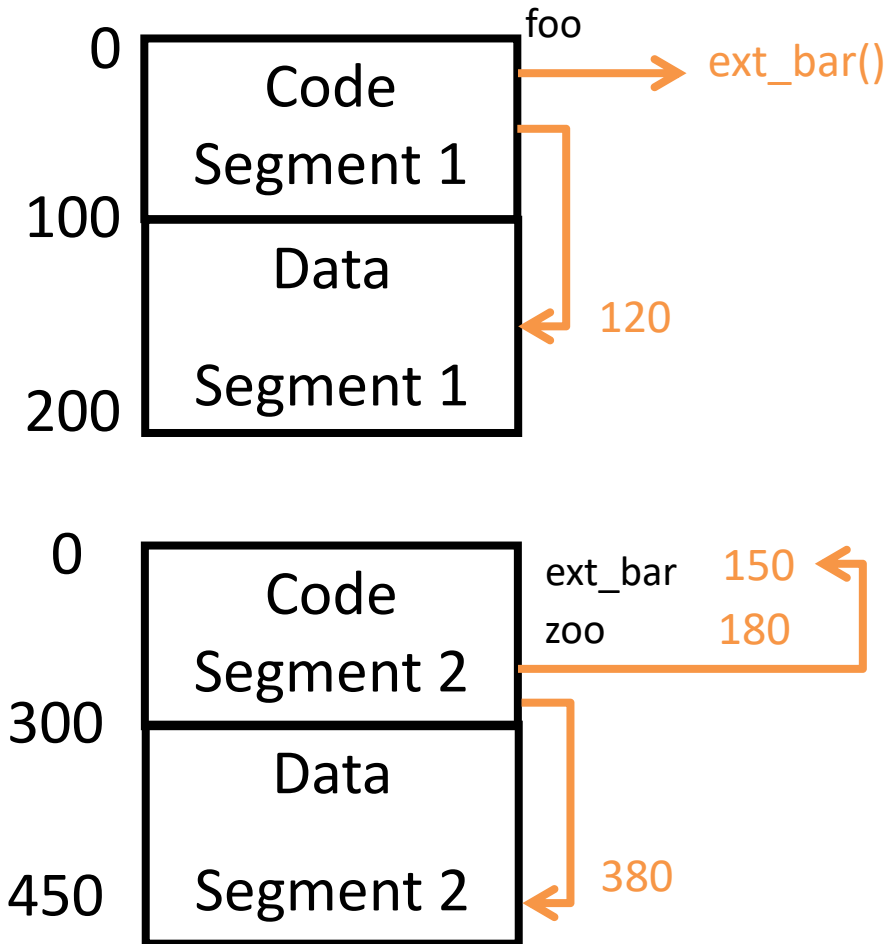

Assembler Summary

- Converts symbolic machine code to binary
 - `addl %edx, %ecx` \Rightarrow 000 0001 11 010 001 = 01 D1 (Hex)
- Format conversions
 - 3 \rightarrow 0x0..011 or 0x000000110...0
- Resolves internal addresses
- Some assemblers support overloading
 - Different opcodes based on types

Linker

- Merges object files to an executable
 - Enables separate compilation
- Combine memory layouts of object modules
 - Links program calls to library routines
 - `printf()`, `malloc()`
 - Relocates instructions by adjusting absolute references
 - Resolves references among files

Linker

Relocation information

- Information needed to change addresses
 - Positions in the code which contains addresses
 - Data
 - Code
 - Two implementations
 - Bitmap
 - Linked-lists

External References

- The code may include references to external names (identifiers)
 - Library calls
 - External data
- Stored in external symbol table

Example of External Symbol Table

External symbol	Type	Address
_options	entry point	50 data
__main	entry point	100 code
_printf	reference	500 code
_atoi	reference	600 code
_printf	reference	650 code
_exit	reference	700 code
_msg_list	entry point	300 data
_Out_Of_Memory	entry point	800 code
_fprintf	reference	900 code
_exit	reference	950 code
_file_list	reference	4 data

Example

Linker (Summary)

- Merge several object files
 - Resolve external references
 - Relocate addresses
- User mode
- Provided by the operating system
 - But can be specific for the compiler
 - More secure code
 - Better error diagnosis

Linker Design Issues

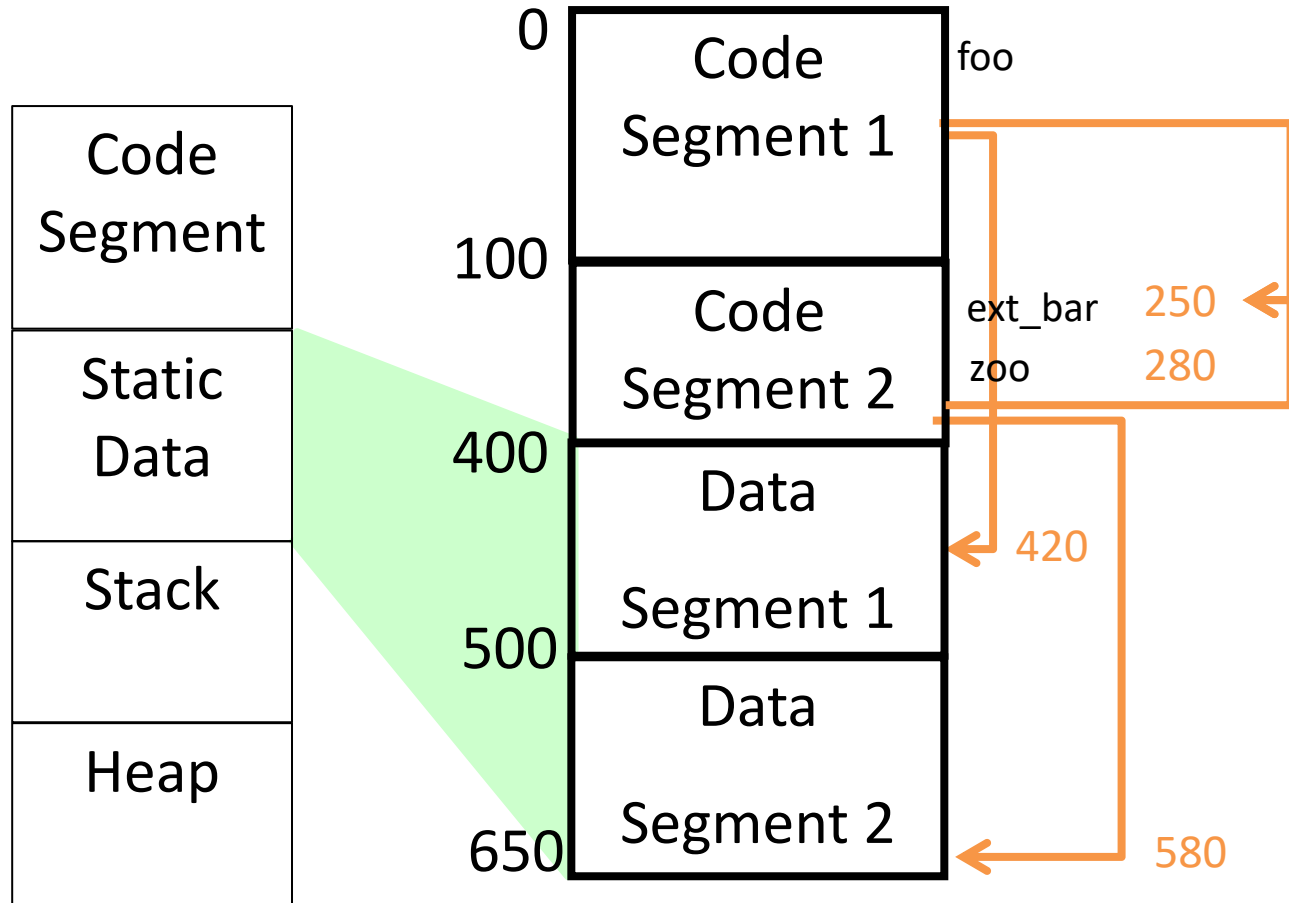

- Merges
 - Code segments
 - Data segments
 - Relocation bit maps
 - External symbol tables
- Retain information about static length
- Real life complications
 - Aggregate initializations
 - Object file formats
 - Large library
 - Efficient search procedures

Loader

- Brings an executable file from disk into memory and starts it running
 - Read executable file's header to determine the size of text and data segments
 - Create a new address space for the program
 - Copies instructions and data into memory
 - Copies arguments passed to the program on the stack
- Initializes the machine registers including the stack ptr
- Jumps to a startup routine that copies the program's arguments from the stack to registers and calls the program's main routine

Program Loading

Registers

Loader (Summary)

- Initializes the runtime state
- Part of the operating system
 - Privileged mode
- Does not depend on the programming language
- “Invisible activation record”

Static Linking (Recap)

- Assembler generates binary code
 - Unresolved addresses
 - Relocatable addresses
- Linker generates executable code
- Loader generates runtime states (images)

Dynamic Linking

- Why dynamic linking?
 - Shared libraries
 - Save space
 - Consistency
 - Dynamic loading
 - Load on demand

What's the challenge?

Source program

Compiler

Assembly lang. program (.s)

Assembler

Machine lang. Module (.o): program (+library) modules

Linker

“compilation” time

Executable (“.exe”):

“execution” time

Loader

Image (in memory):

Libraries (.o)
(dynamic linking)

Position-Independent Code (PIC)

- Code which does not need to be changed regardless of the address in which it is loaded
 - Enable loading the same object file at different addresses
 - Thus, shared libraries and dynamic loading
- “Good” instructions for PIC: use relative addresses
 - relative jumps
 - reference to activation records
- “Bad” instructions for : use fixed addresses
 - Accessing global and static data
 - Procedure calls
 - Where are the library procedures located?

How?

“All problems in computer science can be solved by another level of indirection”

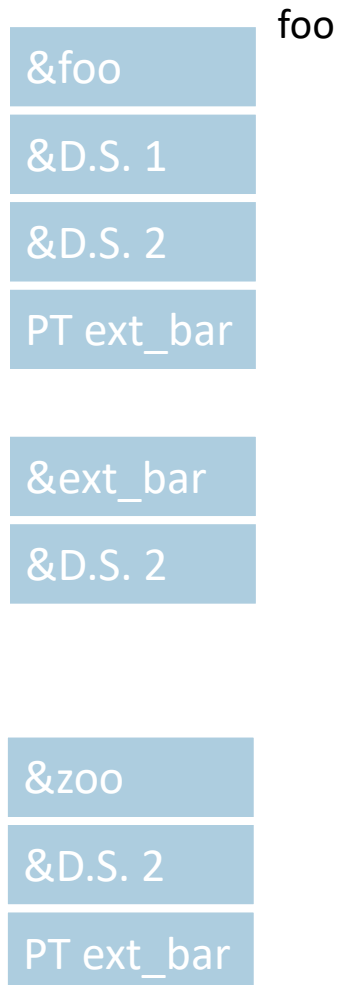

Butler Lampson / David Wheeler

PIC: The Main Idea

- Keep the global data in a table
- Refer to all data relative to the designated register

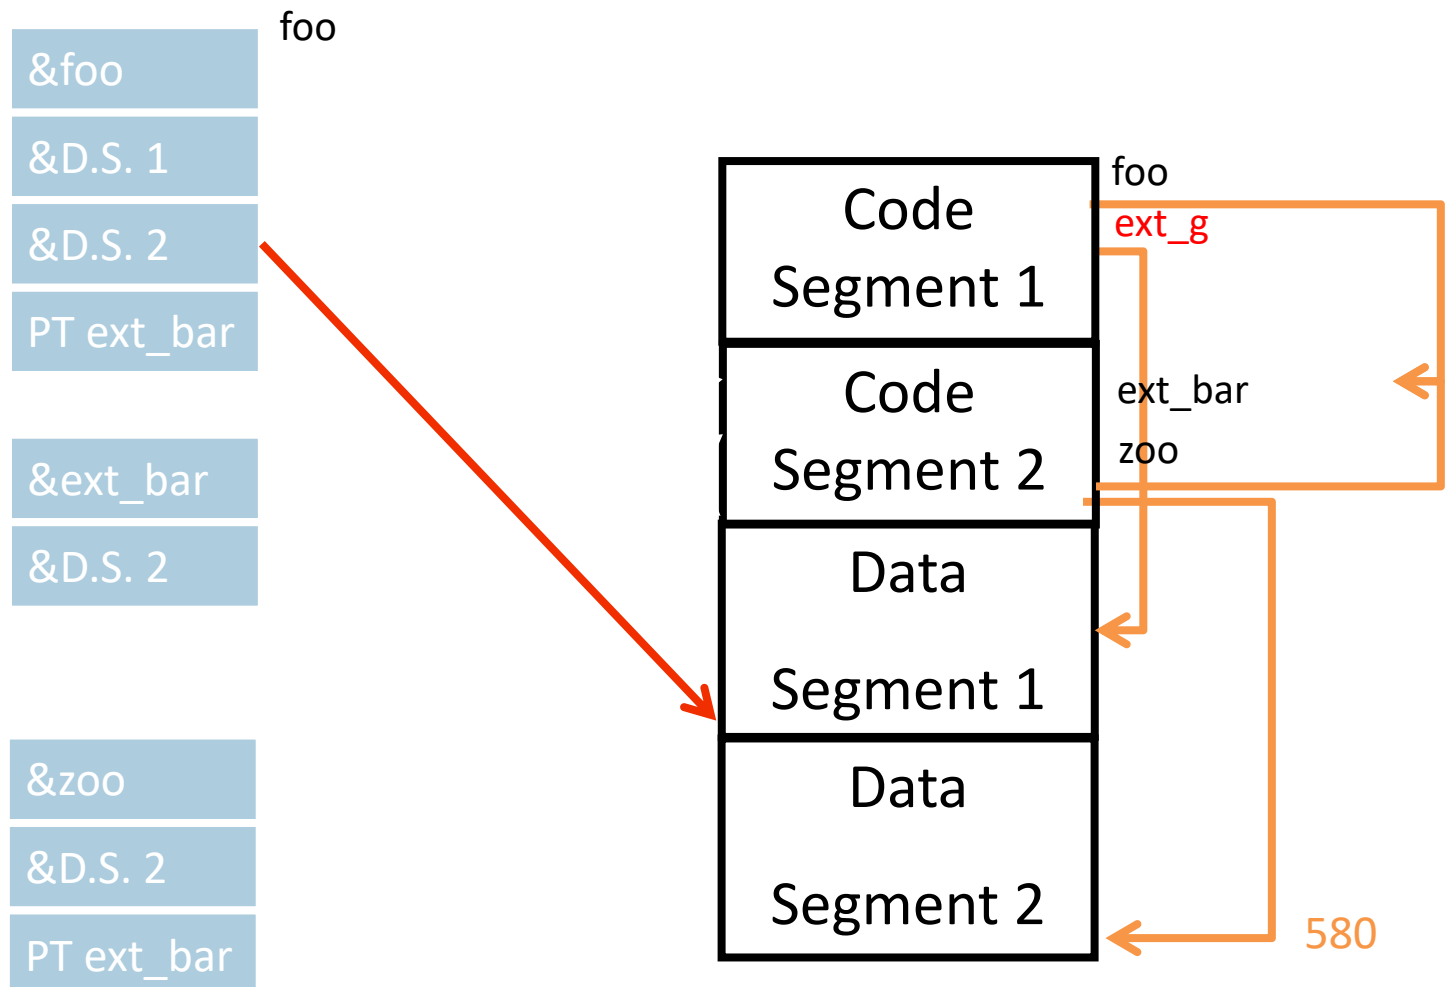

Per-Routine Pointer Table

- Record for every routine in a table

Per-Routine Pointer Table

- Record for every routine in a table

Per-Routine Pointer Table

- Record for every routine in a table
- Record used as a address to procedure

Caller:

1. Load Pointer table address into RP
2. Load Code address from $0(RP)$ into RC
3. Call via RC

Callee:

1. RP points to pointer table
2. Table has addresses of pointer table for sub-procedures

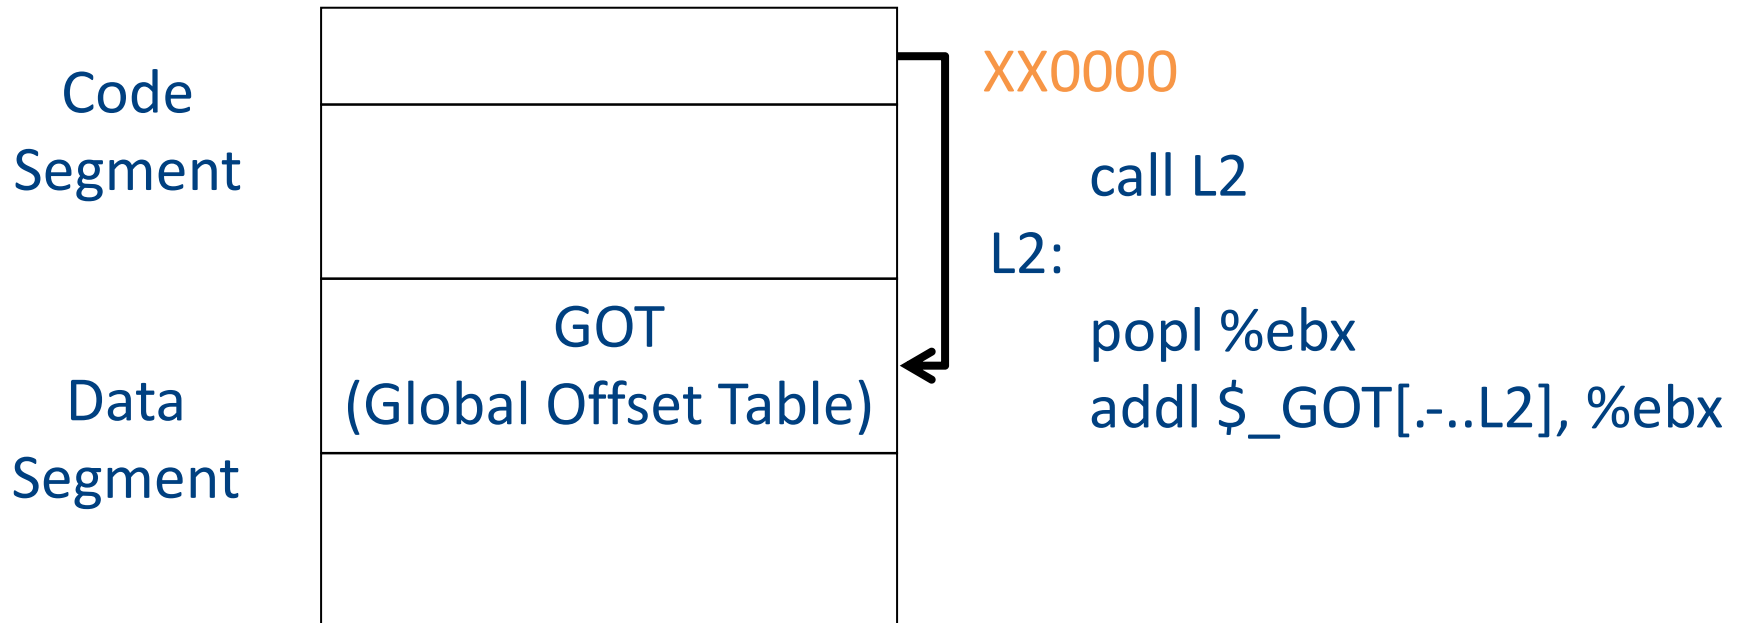

PIC: The Main Idea

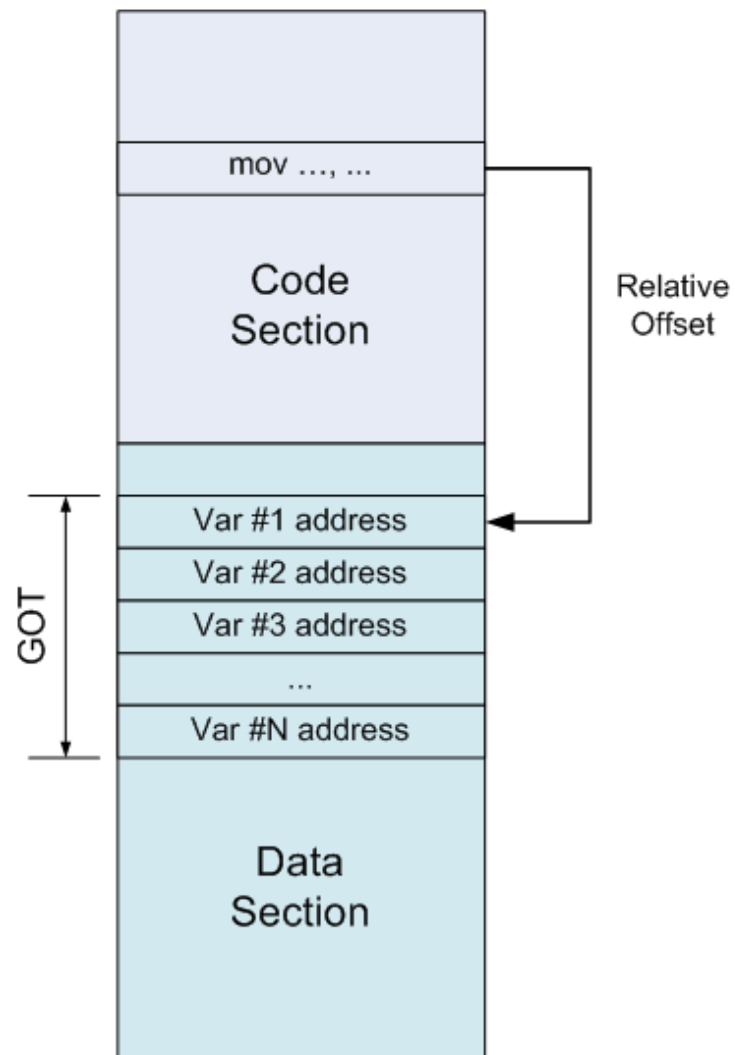

- Keep the global data in a table
- Refer to all data relative to the designated register
- Efficiency: use a register to point to the beginning of the table
 - Troublesome in CISC machines

ELF-Position Independent Code

- Executable and Linkable code Format
 - Introduced in Unix System V
- Observation
 - Executable consists of code followed by data
 - The offset of the data from the beginning of the code is known at compile-time

ELF: Accessing global data

ELF: Calling Procedures (before 1st call)

ELF: Calling Procedures (after 1st call)

PIC benefits and costs

- Enable loading w/o relocation
- Share memory locations among processes

- Data segment may need to be reloaded
- GOT can be large
- More runtime overhead
- More space overhead

Shared Libraries

- Heavily used libraries
- Significant code space
 - 5-10 Mega for print
 - Significant disk space
 - Significant memory space
- Can be saved by sharing the same code
- Enforce consistency
- But introduces some overhead

- Can be implemented either with static or dynamic loading

Content of ELF file

Consistency

- How to guarantee that the code/library used the “right” library version

Loading Dynamically Linked Programs

- Start the dynamic linker
- Find the libraries
- Initialization
 - Resolve symbols
 - GOT
 - Typically small
 - Library specific initialization
- Lazy procedure linkage

Microsoft Dynamic Libraries (DLL)

- Similar to ELF
- Somewhat simpler
- Require compiler support to address dynamic libraries
- Programs and DLL are Portable Executable (PE)
- Each application has its own address
- Supports lazy bindings

Dynamic Linking Approaches

- Unix/ELF uses a single name space and MS/PE uses several name spaces
- ELF executable lists the names of symbols and libraries it needs
- PE file lists the libraries to import from other libraries
- ELF is more flexible
- PE is more efficient

Costs of dynamic loading

- Load time relocation of libraries
- Load time resolution of libraries and executable
- Overhead from PIC prolog
- Overhead from indirect addressing
- Reserved registers

Summary

- Code generation yields code which is still far from executable
 - Delegate to existing assembler
- Assembler translates symbolic instructions into binary and creates relocation bits
- Linker creates executable from several files produced by the assembly
- Loader creates an image from executable
