

Sprint 2018

JavaScript

John Mitchell

Adapted by Mooly Sagiv

Simple Example

```
<!DOCTYPE html>
```

```
<html>
```

```
<body>
```

```
<h1>My First Web Page</h1>
```

```
<script>
```

```
document.write("<p>My First JavaScript</p>");
```

```
</script>
```

```
</body>
```

```
</html>
```

Another Example

```
<!DOCTYPE html>
```

```
<html>
```

```
<body>
```

```
<h1>My First Web Page</h1>
```

```
<p id="demo">My First Paragraph.</p>
```

```
<script>
```

```
document.getElementById("demo").innerHTML="My First JavaScript";
```

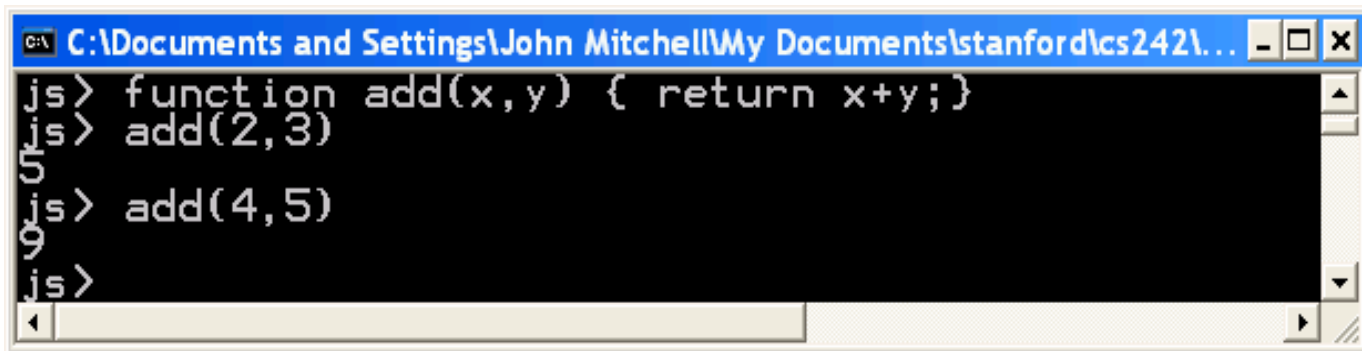

```
</script>
```

```
</body>
```

```
</html>
```

Stand-alone implementation

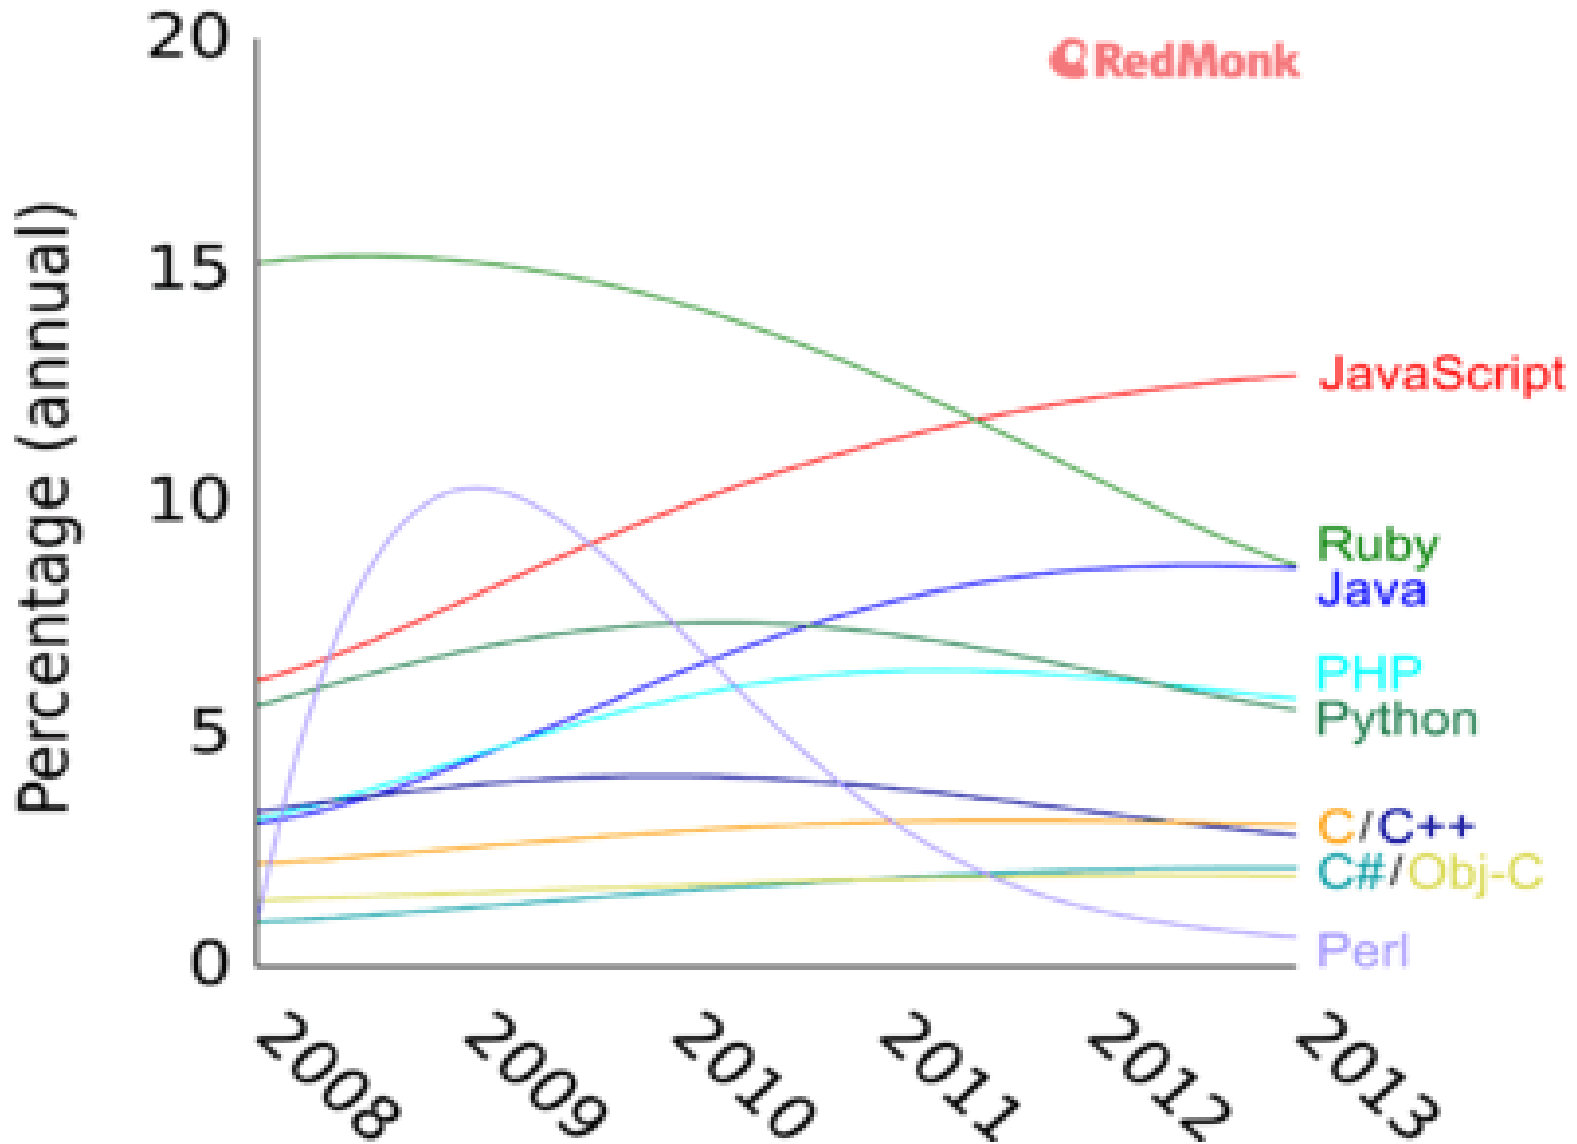

- Spidermonkey command-line interpreter
 - Read-eval-print loop
 - Enter declaration or statement
 - Interpreter executes
 - Displays value
 - Returns to input state

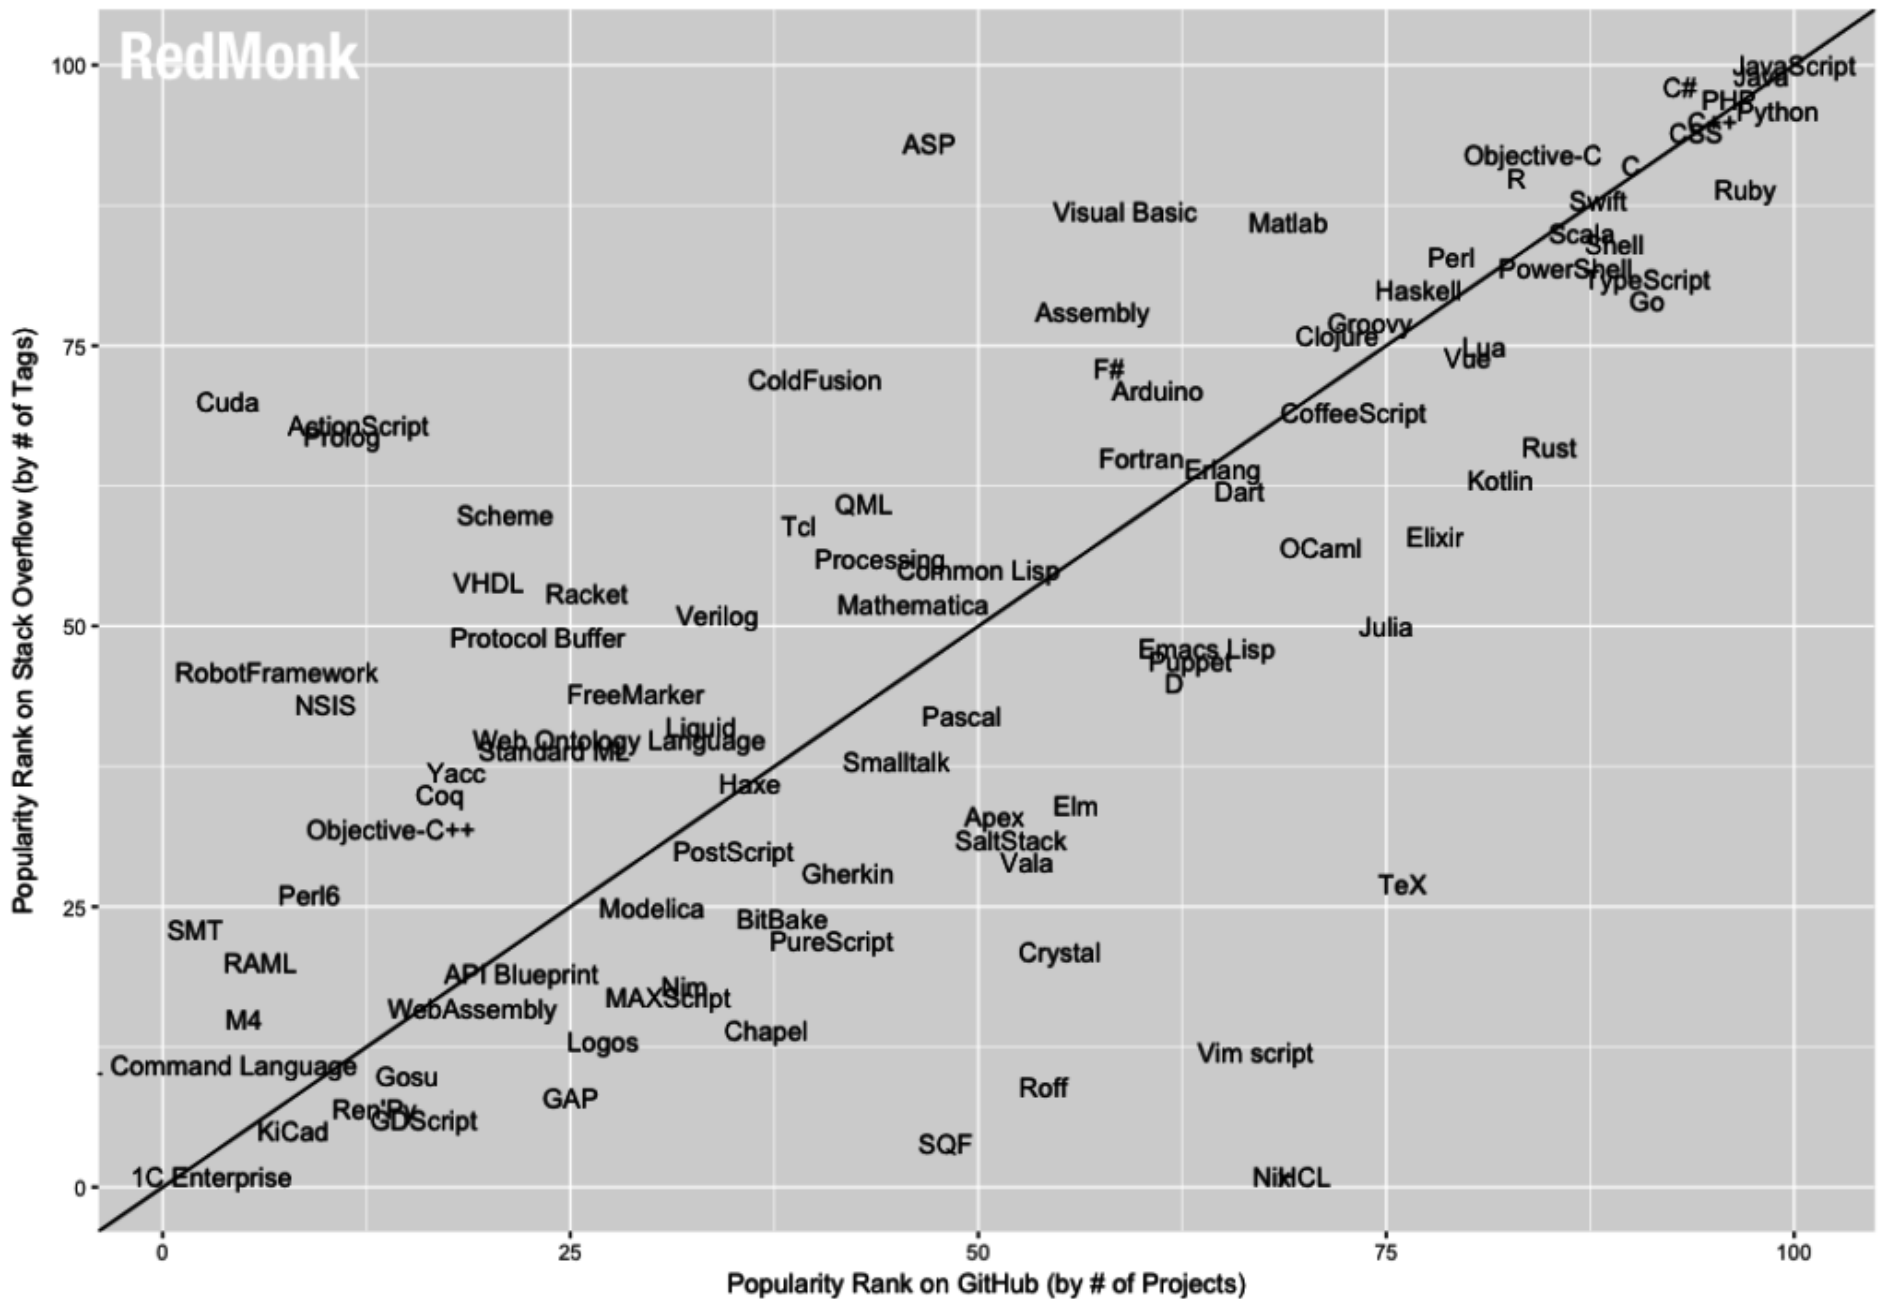

```
C:\Documents and Settings\John Mitchell\My Documents\stanford\lcs242\... - [ ] X
js> function add(x,y) { return x+y;}
js> add(2,3)
5
js> add(4,5)
9
js>
```

New GitHub repositories

RedMonk

RedMonk Q118 Programming Language Rankings

Why talk about JavaScript?

- Very widely used, and growing
 - Web pages, AJAX, Web 2.0
 - Increasing number of web-related applications
 - Adapted as a general purpose programming language
- Illustrates core PL concepts
 - First-class functions
 - Objects, in a pure form
- Some interesting trade-offs and consequences
 - Powerful modification capabilities
 - Add new method to object, redefine prototype, access caller ...
 - Difficult to predict program properties in advance
 - Challenge for programmers, implementation, security, correctness

Keys to Good Language Design

- **Motivating application**
 - C: systems prog, Lisp: symbolic computation, Java: set-top box, JavaScript: web scripting
- **Abstract machine**
 - Underlying data structures that programs manipulate
 - JavaScript: web page -> document object model
- **Theoretical considerations**
 - ECMA Standard specifies semantics of JavaScript

What's a scripting language?

- One language embedded in another
 - A scripting language is used to write programs that produce inputs to another language processor
 - Embedded JavaScript computes HTML input to the browser
 - Shell scripts compute commands executed by the shell
- Common characteristics of scripting languages
 - String processing – since commands often strings
 - Simple program structure
 - Avoid complicated declarations, to make easy to use
 - Define things “on the fly” instead of elsewhere in program
 - Flexibility preferred over efficiency, safety
 - Is lack of safety a good thing? Maybe not for the Web!
 - Small programs

JavaScript History

- Developed by Brendan Eich at Netscape, 1995
 - Scripting language for Navigator 2
- Later standardized for browser compatibility
 - ECMAScript Edition 3 (aka JavaScript 1.5) -> ES5, ...
- Related to Java in name only
 - Name was part of a marketing deal
- Various implementations available
 - Spidermonkey interactive shell interface
 - Rhino: <http://www.mozilla.org/rhino/>
 - Browser JavaScript consoles

Motivation for JavaScript

- Netscape, 1995
 - Netscape > 90% browser market share
 - Opportunity to do “HTML scripting language”
 - Brendan Eich
 - “ I hacked the JS prototype in ~1 week in May
And it showed! Mistakes were frozen early
Rest of year spent embedding in browser” - ICFP talk, 2005
- Common uses of JavaScript have included:
 - Form validation
 - Page embellishments and special effects
 - Dynamic content manipulation
 - Web 2.0: functionality implemented on web client
 - Significant JavaScript applications: Gmail client, Google maps

Design goals

- Brendan Eich's 2005 ICFP talk
 - Make it easy to copy/paste snippets of code
 - Tolerate “minor” errors (missing semicolons)
 - Simplified onclick, onmousedown, etc., event handling, inspired by HyperCard
 - Pick a few hard-working, powerful primitives
 - First class functions for procedural abstraction
 - Objects everywhere, prototype-based
 - Leave all else out!

JavaScript design

- Functions based on Lisp/Scheme
 - first-class inline higher-order functions
function (x) { return x+1; } $\equiv \lambda x. x+1$
- Objects based on Smalltalk/Self
 - var pt = {x : 10, move : function(dx){this.x += dx}}
 - Functions are also objects
- Lots of secondary issues ...
 - “In JavaScript, there is a beautiful, elegant, highly expressive language that is buried under a steaming pile of good intentions and blunders.”

Douglas Crockford

Sample “details”

- Which declaration of g is used?

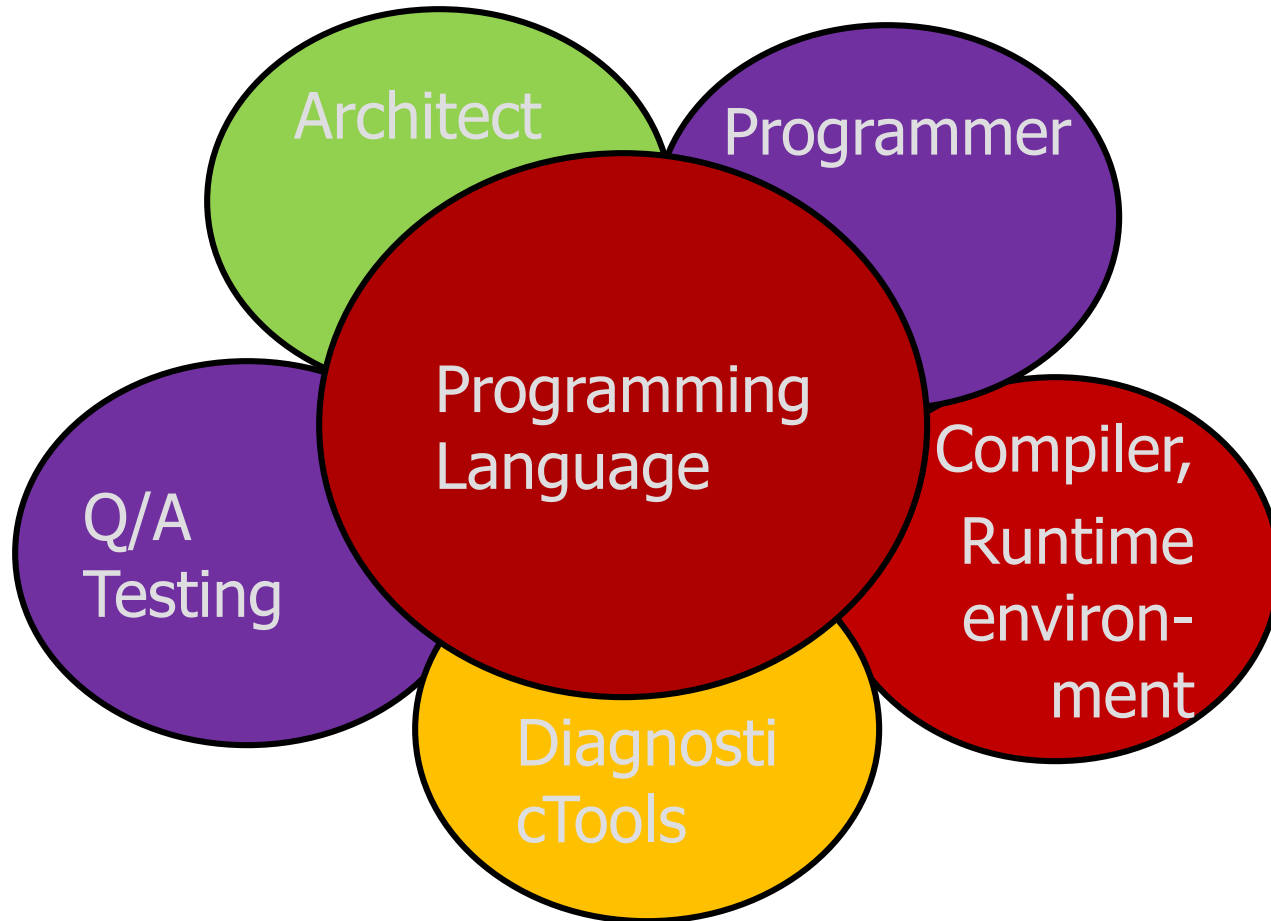

```
var f = function(){ var a = g();  
    function g() { return 1;};  
    function g() { return 2;};  
    var g = function() { return 3;}  
    return a;}  
var result = f();    // what is result?
```

```
var scope = "global";  
function f() { print(scope);  
    var scope = "local";  
    print(scope);  
}
```

// variable initialized here
//but defined throughout f

What makes a good programming language design?

Language syntax

- JavaScript is case sensitive
 - HTML is not case sensitive; `onClick`, `ONCLICK`, ... are HTML
- Statements terminated by returns or semi-colons (;)
 - `x = x+1;` same as `x = x+1`
 - Semi-colons can be a good idea, to reduce errors
- “Blocks”
 - Group statements using `{ ... }`
 - Not a separate scope, unlike other languages (see later slide)
- Variables
 - Define a variable using the `var` statement
 - Define implicitly by its first use, which must be an assignment
 - Implicit definition has global scope, even if it occurs in nested scope

Web example: page manipulation

- Some possibilities
 - createElement(elementName)
 - createTextNode(text)
 - appendChild(newChild)
 - removeChild(node)
- Example: Add a new list item:

```
var list = document.getElementById('list1')
var newItem = document.createElement('li')
var newText = document.createTextNode(text)
list.appendChild(newItem)
newItem.appendChild(newText)
```

This example uses the browser Document Object Model (DOM)
We will focus on JavaScript as a language, not its use in the browser

Web example: browser events

```
<script type="text/JavaScript">  
  function whichButton(event) {  
    if (event.button==1) {  
      alert("You clicked the left mouse button!") }  
    else {  
      alert("You clicked the right mouse button!")  
    }  
  }  
</script>  
...  
<body onmousedown="whichButton(event)">  
...  
</body>
```

Mouse event causes
page-defined function to
be called

Other events: onLoad, onMouseMove, onKeyPress, onUnload

JavaScript primitive datatypes

- Boolean
 - Two values: *true* and *false*
- Number
 - 64-bit floating point, similar to Java double and Double
 - No integer type
 - Special values *NaN* (not a number) and *Infinity*
- String
 - Sequence of zero or more Unicode characters
 - No separate character type (just strings of length 1)
 - Literal strings using ' or " characters (must match)
- Special values
 - *null* and *undefined*
 - *typeof(null) = object; typeof(undefined)=undefined*

Type Checking

- Static types (Algol, C, Java, OCaml)
 - The type of expressions are checked at compile-time
- Dynamic types (lisp, scheme)
 - The type of expressions are checked at runtime
 - Soft typing can be used
- Duck-Typing (Python, Ruby, Javascript)
 - If an object can walk and swim like a duck, it is treated as a duck

JavaScript blocks

- Use { } for grouping; not a separate scope

```
var x = 3;  
x;  
{ var x = 4 ; x }  
x;
```

- Not blocks in the sense of other languages
 - Only function calls and the *with* statement introduce a nested scope

JavaScript functions

- Declarations can appear in function body
 - Local variables, “inner” functions
- Parameter passing
 - Basic types passed by value, objects by reference
- Call can supply any number of arguments
 - `functionname.length` : # of arguments in definition
 - `functionname.arguments.length` : # args in call
- “Anonymous” functions (expressions for functions)
 - `(function (x,y) {return x+y}) (2,3);`
- Closures and Curried functions
 - `function CurAdd(x){ return function(y){return x+y} };`

More explanation on next slide

Function Examples

- Curried function

```
function CurriedAdd(x){ return function(y){ return x+y} };  
g = CurriedAdd(2);  
g(3)
```

- Variable number of arguments

```
function sumAll() {  
  var total=0;  
  for (var i=0; i< sumAll.arguments.length; i++)  
    total+=sumAll.arguments[i];  
  return(total);  
}  
sumAll(3,5,3,5,3,2,6)
```

Recursion

```
var hanoi = function hanoi(disc, src, aux, dst) {  
  if (disc > 0) {  
    hanoi(disc -1, src, dst, aux);  
    document.writeln('Move disc' + disc +  
      'from' + src + ' `dst ` + dst);  
    hanoi(disc -1, aux, src, dst) ;  
  }  
}
```

```
var walk_the_DOM = function walk(node, func) {  
  func(node);  
  node = node.firstChild;  
  while (node) {  
    walk(node, func);  
    node = node.nextSibling;  
  }  
}
```

Use of anonymous functions

- Simulate blocks by function definition and call

```
var u = { a:1, b:2 }
```

```
var v = { a:3, b:4 }
```

```
(function (x,y) {                                     // “begin local block”
```

```
    var tempA = x.a; var tempB =x.b; // local variables
```

```
    x.a=y.a; x.b=y.b;
```

```
    y.a=tempA; y.b=tempB
```

```
}) (u,v)                                             // “end local block”
```

```
// Side effects on u,v because objects are passed by reference
```

- Anonymous functions very useful for callbacks

```
setTimeout( function(){ alert("done"); }, 10000)
```

Objects

- Primitive types are immutable
- An object is a collection of named properties (mutable)
 - Simplistic view in some documentation: hash table or associative array
 - Can define by set of name:value pairs
 - `objBob = {name: "Bob", grade: 'A', level: 3};`
 - New properties can be added at any time
 - `objBob.fullname = 'Robert';`
 - A property of an object may be a function (=method)
- Functions are also objects
 - A function defines an object with method called “()”

```
function max(x,y) { if (x>y) return x; else return y;};  
max.description = “return the maximum of two arguments”;
```

Basic object features

- Creating and modifying objects

```
function Rectangle(w, h) = {this.width=w; this.height=h;}  
var r = new Rectangle(8.5, 11);  
r. area = function () { return this.width * this.height ;}  
var a = r. area;
```

- Better to do it in the constructor

```
function Rectangle(w, h) {  
    this.width = w; this.height = h ;  
    this. area = function () { return this.width * this.height ;}  
}  
var r = new Rectangle(8.5, 11);  
var a = r.area() ;
```

Code and data can be shared via Prototypes

- Each object linked to prototype object
- Rectangle with shared area computation

```
function Rectangle(w, h) {  
    this.width = w; this.height = h ;  
}  
Rectangle.prototype.area= function() {  
    return this.width * this.height ;}  
var r = new Rectangle(8.5, 11);  
var a = r.area() ;
```

Inheritance

- Javascript supports Prototype-based programming
 - As opposed to Java classes
- No need for casting
- Provides a reach set of code reuse patterns
- But syntax is ugly
 - See Javascript the good parts

Changing Prototypes

- Use a function to construct an object

```
function Car(make, model, year) {  
  this.make = make;  
  this.model = model;  
  this.year = year;  
}
```

- Objects have prototypes, can be changed

```
var c = new Car("Tesla","S",2014);  
Car.prototype.print = function () {  
  return this.year + " " + this.make + " " + this.model;}  
c.print();
```

Objects and *this*

- Property of the activation object for function call
 - In most cases, *this* points to the object which has the function as a property (or “method”)
 - Example :

```
var o = {x : 10, f : function(){return this.x}}  
o.f();  
10
```

this is resolved dynamically when the method is executed

JavaScript functions and *this*

```
var x = 5; var y = 5;  
function f() {return this.x + y;}  
var o1 = {x : 10}  
var o2 = {x : 20}  
o1.g = f; o2.g = f;  
o1.g() → 15  
o2.g() → 25  
var f1 = o1.g ; f1() → 10
```

Both o1.g and o2.g refer to the same function.

Why are the results for o1.g() and o2.g() different ?

Local variables stored in “scope object”

Special treatment for nested functions

```
var x = 8
```

```
var o = { x: 10,
```

```
    f : function() {
```

```
        function g(){ return this.x } ;
```

```
        return g();
```

```
    }
```

```
};
```

```
o.f()
```

function g gets the global object as its this property !

Language features

- Stack memory management
 - Parameters, local variables in activation records
- Garbage collection
 - Automatic reclamation of inaccessible memory
- Closures
 - Function together with environment (global variables)
- Exceptions
 - Jump to previously declared location, passing values
- Object features
 - Dynamic lookup, Encapsulation, Subtyping, Inheritance

Stack memory management

- Local variables in activation record of function

```
function f(x) {  
    var y = 3;  
    function g(z) { return y+z;};  
    return g(x);  
}
```

```
var x= 1; var y =2;
```

```
f(x) + y;
```

Closures

- Return a function from function call

```
function f(x) {  
    var y = x;  
    return function (z){y += z; return y;}  
}  
var h = f(5);  
h(3);
```

- Can use this idea to define objects with “private” fields

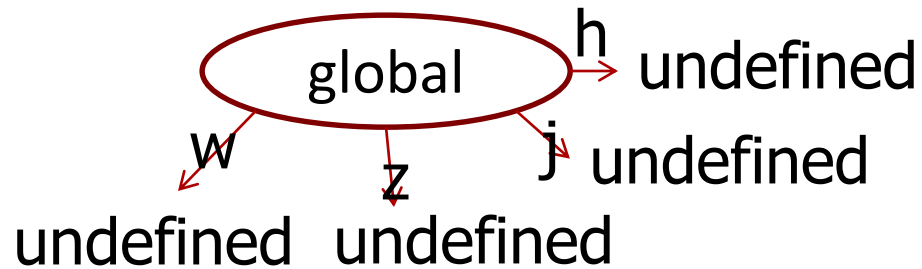

```
uniqueId function () {  
    if (!arguments.callee.id) arguments.callee.id=0;  
    return arguments.callee.id++;  
};
```

- Can implement breakpoints

Implementing Closures

```
function f(x) {  
  function g(y) { return x + y; };  
  return g ;  
}
```

```
var h = f(3);  
var j = f(4);  
var z = h(5);  
var w = j(7);
```

Implementing Closures(1)

```
function f(x) {  
  function g(y) { return x + y; };  
  return g ;  
}
```

```
var h = f(3);  
var j = f(4);  
var z = h(5);  
var w = j(7);
```

Implementing Closures(2)

```
function f(x) {  
  function g(y) { return x + y; };  
  return g ;  
}
```

```
var h = f(3);  
var j = f(4);  
var z = h(5);  
var w = j(7);
```

Implementing Closures(3)

```
function f(x) {  
  function g(y) { return x + y; };  
  return g ;  
}
```

```
}  
var h = f(3);  
var j = f(4);  
var z = h(5);  
var w = j(7);
```

Implementing Closures(4)

```
function f(x) {  
  function g(y) { return x + y; };  
  return g ;  
}  
var h = f(3);  
var j = f(4);  
var z = h(5);  
var w = j(7);  
h= null;
```

Garbage collection

- Automatic reclamation of unused memory
 - Navigator 2: per page memory management
 - Reclaim memory when browser changes page
 - Navigator 3: reference counting
 - Each memory region has associated count
 - Count modified when pointers are changed
 - Reclaim memory when count reaches zero
 - Navigator 4: mark-and-sweep, or equivalent
 - Garbage collector marks reachable memory
 - Sweep and reclaim unreachable memory

Reference http://www.unix.org.ua/oreilly/web/jscript/ch11_07.html

Discuss garbage collection in connection with memory management

Exceptions

- Throw an expression of any type

```
throw "Error2";
```

```
throw 42;
```

```
throw {toString: function() { return "I'm an object!"; } };
```

- Catch

```
try { ...
```

```
  } catch (e if e == "FirstException") {    // do something
```

```
  } catch (e if e == "SecondException") {  // do something else
```

```
  } catch (e){                            // executed if no match above
```

```
}
```

Reference: <http://developer.mozilla.org/en/docs/>

Core_JavaScript_1.5_Guide :Exception_Handling_Statements

Object features

- **Dynamic lookup**
 - Method depends on run-time value of object
- **Encapsulation**
 - Object contains private data, public operations
- **Subtyping**
 - Object of one type can be used in place of another
- **Inheritance**
 - Use implementation of one kind of object to implement another kind of object

Concurrency

- JavaScript itself is single-threaded
 - How can we tell if a language provides concurrency?
- AJAX provides a form of concurrency
 - Create XMLHttpRequest object, set callback function
 - Call request method, which continues asynchronously
 - Reply from remote site executes callback function
 - Event waits in event queue...
 - Closures important for proper execution of callbacks
- Another form of concurrency
 - use setTimeout to do cooperative multi-tasking
 - Maybe we will explore this in homework ...

Unusual features of JavaScript

- Some built-in functions
 - Eval (next slide), Run-time type checking functions, ...
- Regular expressions
 - Useful support of pattern matching
- Add, delete methods of an object dynamically
 - Seen examples adding methods. Do you like this? Disadvantages?
 - `myobj.a = 5; myobj.b = 12; delete myobj.a;`
- Redefine native functions and objects (incl undefined)
- Iterate over methods of an object
 - `for (variable in object) { statements }`
- With statement (“considered harmful” – why??)
 - `with (object) { statements }`

JavaScript eval

- Evaluate string as code
 - The eval function evaluates a string of JavaScript code, in scope of the calling code
- Examples

```
var code = "var a = 1";  
eval(code); // a is now '1'  
var obj = new Object();  
obj.eval(code); // obj.a is now 1
```
- Most common use
 - Efficiently deserialize a large, complicated JavaScript data structures received over network via XMLHttpRequest
- What does it cost to have eval in the language?
 - Can you do this in C? What would it take to implement?

jQuery

- A JS library that simplifies programming
- Database like query languages

Other code/string conversions

- String computation of property names

```
var m = "toS"; var n = "tring";  
Object.prototype[m + n] = function(){return undefined};
```

- In addition

- `for (p in o){....}`
- `o[p]`
- `eval(...)`

allow strings to be used as code and vice versa

Sample Javascript delights

- return
 {
 status: true
 };
- var length = 3;
 console.log(lenght);
- What does “a + b” mean
- False values: 0, Nan, “, false, null, undefined

Lessons Learned

- Few constructs make a powerful language
- Simplifies the interpreter
- But the interaction can be hard to understand for programmers
 - JSLint
- Performance problems
 - JIT compilers
 - Spider Monkey, Mozilla, Safari, Chrome
- Some efforts to create safe Javascript sub-language
 - Adsafe
 - Dart
 - Sandboxing
 - WebAssembly
